In spite of the best endeavors of those interested, lightning-rods constructed in accordance with Franklin's principle have not furnished satisfactory protection. The reason for this is apparent when it is considered that this electrical energy existing in the atmosphere before the discharge, or, more exactly, in the column of dielectric from the cloud to the earth, reaches its maximum value on the surface of the conductors that chance to be within the column of dielectric; so that the greatest display of energy will be on the surface of the very lightning-rods that were meant to protect, and damage results, as so often proves to be the case. The very existence of such a mass of metal as an old lightning-rod only tends to produce a disastrous dissipation of electrical energy upon its surface,—"to draw down the lightning," as it is so commonly put.

Having cleared our minds, therefore, of any idea of conducting electricity, and keeping clearly in view the fact that in providing protection against lightning we must furnish some means by which the electrical energy may be harmlessly dissipated, it seems clear why it is that the use of sufficient energy to dissipate a pound of copper, leaves not enough to do harm to other objects around. The question naturally arises how much energy there is available. There is stored up in each cubic centimeter of the column of dielectric from the cloud to the earth, just before the lightning-discharge, an amount of electrical energy given by the expression $\frac{1}{8\pi} K E^2$, where K is the specific inductive capacity of the dielectric, E the electromotive intensity, both in electrostatic units. This expression is given on p. 156, Vol. I., second edition, of Maxwell's "Treatise on Electricity and Magnetism." Substituting the values of K and E, and reducing, we find that the amount of energy involved amounts very nearly to one foot-pound for each cubic foot of air. This is, of course, a maximum value.

According to the usually accepted theories of electrical action, this electrical energy is gradually stored up in the column of dielectric from the cloud to the earth, and is distributed in this column with the greatest amount per cubic foot along some central core, this amount not exceeding one foot-pound per cubic foot, and this process can be continued until the stress is so great that the air breaks down, when what we call a discharge of lightning takes place, and the electrical energy disappears, of course only to take on some other form. You may say that the electricity travels from the cloud to the earth, or from the earth to the cloud whichever you please; at any rate, there is an electrical action in a vertical direction, the discharge being supposed vertical. I will ask, however, whether it is not true that the energy involved travels along the equipotential lines; that is, travels in the main horizontally. It seems to me that it shrinks in, as it were from the considerable column or ellipsoid of dielectric upon the central core, where it manifests itself as heat and light in the electrical flash. It will, then, be clear how it is that in providing a body upon which the dissipation of energy shall take place we had to guard against something not coming from above or below, but coming from the side, and that this may be the explanation of why it is that, so far as I have been able to find, a dissipatable conductor protects the building between two essentially plane surfaces passing through its upper and lower ends.

The main point which I would urge upon your consideration is that by giving the electrical energy something which experience shows it would readily dissipate, that is, a conductor of varying resistance and small size, we can but mitigate the effects of lightning-discharges, so long as the conservation of energy holds true. I will only repeat that I have so for found no case on record where the dissipation of such a conductor has failed to protect the building under the conditions already explained.

Letters to the Editor.

RULES AND FORMULÆ FOR INCANDESCENT LAMP WIRING.

In the issue of April 29, I notice some remarks concerning my communication which appeared in the issue of April 15. I will say that Mr. Pike has certainly cleared up the subject in a very simple and practical manner.

I confess that my statement, regarding a theoretically perfect system, should have been given with some reserve.

However, I am glad to be corrected in the matter, and hope next time I will discuss more of the possible instead of the impossible.

OSBORN P. LOOMIS.

BROOKLYN, N. Y, April 29, 1891.

METHOD OF FASTENING BASES TO INCANDESCENT LAMPS.

Will you kindly inform me of a formula for some compound used as a cement to fasten on the bases to incandescent lamp bulbs. Any further information on the same subject would be of value to me.

ALFRED C. TEVIS.

Haverford College, Haverford P. O., Pa.

ANSWER:

Lamp.—The lamp should have either a roughened surface on glass, or glass horns should be melted on when the carbon is sealed in, to insure no movement between bulb and base when finished.

Mould.—The mould is preferably made of brass in two parts; before placing in the rack it should be wiped with oil; then the parts forming the base or sockets should be placed in the mould, being sure that the parts are perfectly free from oil where the plaster comes in contact.

Compound.—Mix plaster of Paris with water to a consistency of cream; then pour into the mould which has been previously prepared.

Method of Handling.—Pull lamp down into the mixture in mould, being sure to separate the wires, and placing them according to form of base used before doing so; keep the bulb in a perfectly vertical position to insure the base being true on lamp; when the plaster has set, take the mould off and place the lamp in a room or oven where the temperature does not exceed 95° F., so that the plaster dries gradually; if dried too quickly it will crack. After being dried for about 20 hours, trim off and white shellac the exposed plaster.

PHILLIPS, ME.—At the annual meeting of the stockholders of the Sandy River Telegraph Co., the following officers were elected: E. J. Gilkey, president; Harry P. Dill, clerk and treasurer; E. J. Gilkey, Wm. Bates, G. D. Austin, Joel Wilbur, D. H. Toothaker, directors. A dividend of $1.25 per share was declared.

Society and Club Notes.

ANNUAL AND GENERAL MEETING OF THE AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

The Spring meetings of the Institute will be held on May 19th, 20th and 21st, at its headquarters, No. 12 West 31st street, New York city. The preliminary programme as arranged by the Committee on Papers and Meetings, and the Local Committee of Arrangements, is as follows: The regular monthly meeting of the council will be held in the secretary's office at 5 P. M., May 19th.

The annual meeting for the presentation of reports, election of officers, and other business will follow at 8 P. M., on the same date. The morning session, May 20th, will assemble at 10 o'clock, when the following papers will be read:

"The Development of the Dynamo," by Prof. Harris J, Ryan; "Evolution of the Stationary Electric Motor," by Dr. S. S. Wheeler; "Some Data Concerning the Photometry of the Arc Lamp," by Prof. E. L. Nichols.

Afternoon session, May 20th, "A new Graphical Method of Calculating Leads for Wiring," by Carl Hering; "Street Car Motor Design," by H. F. Parshall; "A Proposed Electrical Equipment for the Coming Rapid Transit System of New York City," by Frank J. Sprague.

"Some Recent Improvements In Printing Telegraphs," by H. Van Hoevenbergh, illustrated by diagrams and apparatus in operation.

Evening session at Columbia College. Experiments with "Alternating Currents of High Frequency," by Mr. Nikola Tesla.

Thursday morning, May 21st, the members will meet at the Crocker-Wheeler Motor Co.'s factory, 430 West 14th St. After an inspection of this establishment, the meeting will reassemble at 12 West 31st St., when the following papers will be read:

"A New Device for the Measurement of Alternating Current Potential," by Prof. Geo. S. Moler; "A Study of the Fluctuations of E. M. F. in the Open Coil Armature of a Constant Current Machine," by Mr. M. E. Thompson; "Some Results in the Practical Utilization of Electric Welding," by Dr. F. A. C. Perrine.

Afternoon session, May 21st, "Electric Meters," by G. W. Walker; an address by Dr. W. H. Wahl on "The Aluminum Problem, Retrospective and Prospective," also a paper entitled "Shall Aluminum be Alium?' by Mr. Oberlin Smith. In connection with this subject there will be an exhibit of aluminum products.

Thursday evening a reception will be tendered to the Institute by the Electric Club.

Visits to different electrical establishments and objects of interest will also be arranged for Friday, May 22nd, an announcement of which will be published in the official programme.

MAGNETIC CLUB.

A very successful dinner was given by the above club on Wednesday evening last, at Zanghieri & Succho's restaurant, on Sixth avenue. President Cockey was in the chair. The attendance was very large and enthusiastic. After the dinner, which was excellently served, came a programme of speeches, songs, pianoforte music, recitations, &c. The club is rapidly growing in membership and influence.

NEW YORK ELECTRIC CLUB.

A dinner will be given at the club house on May 5, to celebrate the fifth anniversary of the organization. President Insull has taken up the good work begun with such brilliant success by President Madden, and proposes to lift this year a large portion, if not all, of the club's indebtedness. The recent growth in membership is very gratifying as an augury of renewed life and vigor.

NEW YORK ELECTRICAL SOCIETY.

On Thursday, April 30, Mr. Charles Steinmetz, electrician of the Eickemeyer Dynamo Machine Company, delivered a very interesting lecture on "The Elementary Principles of Designing Alternating Current Apparatus," before the Society at Columbia College. Mr. Steinmetz began by pointing out the fact that the first dynamos constructed for practical use were alternating machines, and that for a long time continuous current machines were only used as exciters for the field magnets of the former. He then described various types of modern alternating machines, and showed the manner in which they resembled the older machines. With continuous current machines, remarked Mr. Steinmetz, all that was formerly required was a knowledge of Ohm's law, and, by means of trials and experiments, tolerably good results were obtained; but the work of Hopkinson and Kapp on the magnetic circuit placed the continuous current machine at once within the realm of prime movers which could be calculated exactly before hand.

The discovery of the converter principle in electricity again brought the alternating machine into prominence; but when it became a question of designing alternating current apparatus, such as converters, generators, and motors, difficulty was at once experienced, because alternating currents do not obey Ohm's law and other laws to which the continuous current is subject. Mr. Steinmetz demonstrated this by taking a coil having half ohm resistance, and placing it in a 50 volt alternating circuit. With a continuous current circuit, a current of 100 amperes would have passed through the coil. The ammeter in circuit showed, however, only 10 amperes. He also showed how the introduction of an iron core within the coil decreased the current passing through it, and explained the difference between the cutting down of the current by a rheostat and by self induction. In the one case the energy is entirely absorbed in the rheostat, which dissipates it so far as useful work is concerned; but when cut down by self induction, the energy is merely retransferred to the circuit which is the source of the energy. Mr. Steinmetz likened the difference in these two cases to the shutting off of light by a mirror and by a black screen, respectively. In the one case, the light, while shut off, is reflected towards the original source and is not diminished. With a black screen, however, the light is absorbed and lost for all purposes of illumination.

Mr. Steinmetz then showed the screening action which takes place when the iron core within the coil is surrounded by a closed coil. The latter then absorbs all the energy and is heated, and the primary inducing coil has no effect on the iron core. This shows that the real field of action is outside of the wire, and that the wire is merely a medium which governs the course of the action.

Mr. Steinmetz then showed that under certain circumstances the sum of the currents in two branches of an alternating circuit is greater than that in the main circuit. For this purpose he coupled up three ammeters, one in the main circuit and one each in the two branches, one of which consisted of an inductive resistance and the other of a non-inductive. The current in the two branches respectively was 9 and 9½ amperes, while that in the main circuit was only 14 amperes. Mr. Steinmetz then showed by very simple diagrams that the instantaneous value of the E. M. F. of an alternating current which follows the law of sines when laid out in polar co-ordinates gave points on a circle. He also demonstrated that a combination of sine waves of different phases follows the law of the parallelogram of forces, and that in general any number of sine waves can be resolved into a polygon of forces. Mr. Steinmetz showed how the various phenomena which enter into the operation of converters and alternating apparatus, such as lag due to hysteresis, Foucault currents and self-induction can be worked out graphically, and he also demonstrated graphically that the E. M. F. of mutual induction consumes energy, while that of self induction entails no loss of energy.

In the discussion which followed, Mr. Mailloux pointed out that while the experiment of the branch circuits apparently showed a greater energy in the branches than that in the main circuit, in reality this was not the case, as the power was the product of the current strength into the potential, and that although the currents indicated were greater, the actual energy was not, and hence that the phenomenon was not at varience with the law of the conservation of energy.

Legal Notes.

EDISON FILAMENT CASE.

It is stated that, contrary to expectation, the Edison filament case will now come up for argument, and that Judge Wallace has decided to hear the argument himself when he comes to New York to hold the Equity Term, beginning May 25. It is said also that the Edison company are desirous to push the case all they can.

OBJECTING TO STATE TAXATION.

The Brush Electric Illuminating Company has procured from Judge Patterson of the New York Supreme Court a writ of certiorari to review the action of State Controller Wemple in levying on it, from 1881 to 1888, a tax amounting to $10,752.50. The tax has been paid, but under protest, the company alleging that it is exempt from State taxation.

College Notes.

UNIVERSITY OF MINNESOTA.

The Minnesota legislature has appropriated $120,000 for extraordinary expenses of the State University. Of this sum $15,000 will be used for the equipment of a school of mines and department of pharmacy. The School of Mines will occupy quarters in Pillsbury Hall and the Engineers' Building. Professors of electrical engineering and of mining engineering will be shortly chosen. Candidates are now being considered by the Executive Committee of the Board of Regents.

Reports of Companies.

THE SENECA FALLS, N. Y. ELECTRIC LIGHT AND POWER STATION.

This station, when completed, will be one of the most solid and substantial for its size in the state. The main shaft, which will be five inches in diameter and over seventy-five feet long, will rest on solid masonry abutments, the foundations of which extend eight or ten feet below ground. To this shaft may be applied direct the force of three 80 h. p. water wheels, one 80 and one 290 h. p. engines, making a total of about 540 h. p. Along on either side of the main shaft will be arranged the dynamos for the different arc light circuits, the incandescent circuit, and the power circuit for the electric railroad, etc. The three water wheels will be controlled by electric governors.

ILLINOIS PULSION TELEPHONE CO.

Under the title of the Illinois Pulsion Telephone Company, a new corporation has just been formed, the incorporators being Carlos J. Ward, Ora Ensminger and W. H. Palmer, of Chicago. The capital stock is $500,000, about three fourths of which is held in Chicago. The organization is for the purpose of building and leasing lines of private telephones throughout Illinois. As the name suggests, the Pulsion, or acoustic, telephone will be used. The State right has been secured from the Pulsion Telephone Company of New Hampshire, owners of the patent. At the present time Boston is the only city in the country which has a similar company.

KEYSTONE ELECTRIC CO.

The above concern, of Erie, Pa., is now a full fledged corporation. It has a capital stock of $25,000, and its officers are :—J. W. Leech, president and general manager ; C. J. Sturgeon, secretary and superintendent ; J. F. Downing, treasurer. The last named gentleman is a wealthy citizen, and the general manager of two large insurance companies. The Keystone motors, etc., will now be actively pushed, and a large business is confidently expected. The company invite correspondence, and are ready to fill orders with the utmost promptitude.

THE TEXAS SALE OF THE ERIE TELEPHONE CO.

The Boston News Bureau says : "It is understood that the arrangement entered into by the Erie Telephone Company with the Texas syndicate, is in substance an option whereby the syndicate has the privilege of buying a portion or all of the stock of the Southwestern Company owned by the Erie. If a sale is made the proceeds will be divided in extra dividends among the stockholders. The terms are a cash payment for all stocks purchased except $50,000 worth, this to be 20 per cent cash, balance at interest, payable in one year, secured by the stock as collateral. The Erie Company reserved during 1890 a cash surplus of $70,000, which, with a loan of $60,000 has enabled the company to take its proportion of the new stock issued in the sub-companies with the American Bell Telephone Company. The company has an underground plant covering the most important streets in St. Paul, Minneapolis and Cleveland, and conduits in the same cities of 2,000 miles of wire. The new stock issued provided for this. A good authority on Erie Telephone says : Judging the earnings of the company by the surplus earnings of the past nine months the Erie Company will add to its surplus for the fiscal year ending March 31, 1891, about $12,000, and the sub-companies $25,000, making a total surplus for the year $37,000. Seventeen thousand dollars of the $25,000 would be Erie's share, which with the $12,000 would make $29,000. At that rate the floating debt of the company, which amounts to $60,000, would soon be wiped out. The sub-companies have no indebtedness and can incur none without violating the American Bell contract."

DETROIT ELECTRICAL WORKS.

The stock of this enterprising company is being traded in very actively on the Boston Stock Exchange, and has seen a rapid advance in price. President Hugh McMillan of the Detroit Electrical Works is quoted as saying that in 1890, on a capital of $200,000, the company earned $50,000. Mr. McMillan has been assured since he left Detroit, that company would have contracts to equip the railways of Fall River and Lawrence, and Buffalo, N. Y., with the Rae motors, and generators. These contracts are figured as making over $1,000,000 business immediately on hand. The Detroit Works are doing practically a cash business, and not promoting companies. Several well-known Boston men will be added to the board of directors.

DIVIDENDS.

SOUTHBRIDGE, MASS.—A semi-annual dividend of 3 per cent. has been declared by the Gas and Electric Light Company.

THE THOMSON-HOUSTON ELECTRIC CO. has declared a dividend of $1 per share, payable May 15.

STOCKS AND BONDS.

WESTINGHOUSE STOCK is steadily rising on reports of a final adjustment of the company's finances, and it has now passed 15.

Appointments, Etc.

MR. ISAAC P. SAMPSON has been reappointed treasurer of the Athol, Mass., Electric Light Co.

MR. JOSEPH SPRAGUE, assistant superintendent of the Carthage, Mo., Electric Power Co., will hereafter have his headquarters in Cartersville, to operate the plant there.

MR. GEO. B. COLEMAN has become electrician, and Mr. A. B. Prince engineer, at the electric light station at Milford, Mass. Mr. A. H. Shaw of the Thomson-Houston electric works has temporarily filled the position.

MR. W. B. BROWN, has resigned his position as electrician of the Alliance Street Railway Co. of Alliance, O., and has accepted an appointment at increased salary with the Mutual Electric Light Co.

MR. F. MASON has been appointed electrician of the Alliance, O., Street Railway Co.

MR. E. F. CARPENTER has resigned as superintendent of the Gardner, Mass. Electric Co., to accept the position of manager of the United Electric Light Co. of Springfield, Mass., to take effect June 1, next.

MR. G. W. HART, superintendent of the Edison Electric Light Co. of Kansas City, and assistant general manager of the Kansas City Electric Light Co. has resigned these positions in order to devote his energies to the Hart & Hegeman Manufacturing Co. which will manufacture special electric light supplies.

NATIONAL ELECTRIC LIGHT ASSOCIATION.

Mr. J. W. Beane, secretary of the association, has made a trip to Montreal to look over the ground for the convention in that city next August. He found the outlook most promising and made a number of arrangements. The central station companies of Canada and the electrical concerns generally are taking a lively interest in the meeting. The exhibit of electrical goods promises to be large.

Financial Market.

QUOTATIONS ON ELECTRICAL STOCKS.

F. Z. Maguire & Co., Electrical Securities, of 18 Wall street, this city, report the following quotations of May 2, 1891, from New York, Boston and Washington.

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED APRIL 28, 1891.

Accumulators:—

Method of Making Electrodes for Secondary Batteries, H. H. Lloyd, 451,407. Filed Oct. 27, 1890.
Consists in preparing material or materials to constitute the plate, forming the mass in a suitable appliance, and then applying thereto a molten material or materials under a heavy pressure by means of compressed gas or gases to cause the grid or frame to be instantaneously and firmly attached to the plate.

Alarms and Signals:

Electro-Mechanical Gong-Striking Machine, T. F. Gaynor, 451,121. Filed July 25, 1889.
Device for controlling the striking of a gong through the power of a suspended weight or a wound-up spring.

Electric Indicator, J. L. Ricketts, 451,226. Filed Nov. 28, 1890.
An electric annunciator adapted for use in houses, elevators, &c.

Polarized Bell, A. Storer, 451,414. Filed Aug. 7, 1890.
Details of design and construction.

Conductors, Conduits and Insulators:—

Electric Connection, H. J. Brewer, 451,364. Filed Sept. 5, 1890.
Designed to prevent corrosion from moisture or galvanic action at points of contact and especially applicable to battery connections; consists in a conductor terminal in which the wire is surrounded by a sheathing of practically non-corrosive metal, such as tin.

Safety Connection for Electric Conductors, R. H. Gould, 451,377. Filed Sept. 11, 1890.
A safety device intended to obviate danger to life or property by the breaking and falling of a wire between two poles or other supports.

Insulator, R. D. Haines, 451 379. Filed Dec. 12, 1890.
Applicable to the construction of electric conduits; consists in forming a body or core of clay, drying it until it is firm and rigid, then dipping or submerging it in molten glass, or otherwise covering it with glass in a plastic state, and finally annealing the glass plated conduit in a kiln.

Dynamos and Motors:—

Brush Holder for Dynamos, W. LeR. Emmet, 451,177. Filed Sept. 18, 1890.
A device for securing the requisite pressure between the carbon brush and the commutator of a dynamo and providing means for a conveniently adjustable pressure and for maintaining a uniform pressure along the whole face of the brush.

Starting Device for Electric Motors, E. P. Sharpe, 451,212. Filed Dec. 5, 1890.
A rheostatic switch for controlling and graduating the amount of current supplied to a motor.

Armature for Electric Motors and Generators, P. Grant, 451,242. Filed Nov. 28, 1890.
A compound armature-core formed of a number of sections fitting around a shaft and having air spaces between their adjacent edges. It may consist of a number of radial arms, each consisting of a pair of sections with an air space between them.

Regulator for Dynamo Electric Machines, F. Tischendoerfer, 451 312. Filed Dec. 8, 1890.
A method of regulating a dynamo having auxiliary field-magnet poles, consisting in increasing the magnetic effect in the auxiliary field-magnet cores lying next the brushes in the direction of the armature's rotation in sequence and in similarly decreasing said effects in a reverse direction.

Electric Motor, R. Eickemeyer, 451,320. Filed Aug. 28, 1890.
A reciprocating motor. Consists in the combination of a cylindrical shell of magnetic metal, having apertures to receive means for connecting an interior reciprocating element with external mechanism and affording at its inner surface an annular outer pole-face, a field coil or helix enclosed by the shell, and a central core of magnetic metal within the field coil and affording at its outer surface an inner pole face of opposite polarity to that of the outer pole-face.

Galvanic and Thermo-Electric Batteries:—

Electric Battery, J. T. Van Gestel, 451,142 Filed Aug. 29, 1890.
Relates to batteries called "dry batteries." Employs in connection with the positive or carbon electrode a layer or coating of binoxide of manganese or its equivalent applied and united to the surface.

Lamps and Appurtenances:—

Electric Arc Lamp, C. G. Young, 451,101. Filed Jan. 3, 1889.
A lamp designed and constructed to dispense with the tube which in ordinary arc lamps extends upward to provide a protection for a feed rod.

Hanger for Electric Lamps, P. S. Bates, 451,149. Filed Jan. 6, 1891.
A drum and cord arrangement permitting a lamp to be raised or lowered by taking hold of the lamp itself.

Electric Arc Lamp, J. H. R. Ward, 451,189. Filed Dec. 11, 1890.
A toothed rack and pinion feed adapted to be operated with but one magnet.

Electric Arc Lamp, A. G. Waterhouse, 451,250. Filed July 3, 1890.
In addition to the feeding mechanism includes a retarding mechanism provided with a separate clutch to engage the carbon rod and to travel downward with the rod, also a tripping mechanism carried by the retarding mechanism for controlling the position of the clutch.

Insulating Swing Joint, H. P. Drew, 451,300. Filed Jan. 24, 1891.
Provides a connecting joint for gas pipes capable of being turned at various angles and providing electrical insulation in the flexible joint to protect an electric wire running through the pipe where gas and electric light fixtures are mounted together.

Electric Arc Lamp, R. Schefbauer, 451,309. Filed Oct. 3, 1890.
Improvements in the lamp patented to the same inventor Jan. 28, 1890, No 420,311: designed to simplify construction, to bring the mechanism within a smaller space and to render the lamp more sensitive to the varying strength of current.

Measurement:—

Electric Meter, F. K. Irving, 451,125. Filed Oct. 22, 1890.
Records upon a dial, by a pen or pencil, the movement of the core of a solenoid included in the circuit to be measured.

Metallurgical:—

Magnetic Ore Separator, J. P. Conkling, 451,369. Filed Aug. 7, 1889.
Combines with a conveyor, a revolving cylinder consisting of a shell of non-magnetic material, stationary magnets within the cylinder, and pole-pieces adjacent to the surface of the conveyor and made to extend across the conveyor and to connect the various magnets.

Magnetic Ore Separator, J. P. Conkling, 451,370. Filed Sept. 13, 1890.
Employs several sets of electro-magnets rotating with a shaft arranged transversely and above the conveyor, each pole of every magnet having an independent segmental pole-piece forming the arc of a circle and in superficial contact with the internal surface of a non-magnetic cylinder; means are provided for sending current through each of the electro-magnets in a set when presented opposite the conveyor.

Metal Working:

Method of Electric Welding, E. Thomson, 451,345. Filed June 14, 1890.
Particularly applicable to lap-welding and consists in subjecting the parts to be joined to the action of rolls, hammers, dies, or other devices after they have been heated to the proper temperature by an electric current and after the current has been shut off.

Miscellaneous:—

Electric Switch, LeR. S. White, 451,190. Filed Oct. 11, 1890.
Design and construction of a double-pole switch.

Portable Magnetic Riffle, W. C. Edwards, 451,208. Filed Dec. 11, 1890.
Relates to riffles for separating metallic particles from paper pulp, and consists of a series of magnets inclosed in non-magnetic covering and fixed on a base holding the magnet-poles elevated.

System for Electrically Supplying Hot Water for Consumption and Heating Purposes, M. W. Dewey, 451,239. Filed April 5, 1890.
Similar to the invention patented to the same inventor, Feb. 4, 1890, No. 420,641.

Method of and Apparatus for Electrically Supplying Hot Water for Consumption and Heating Purposes, M. W. Dewey, 451,240. Filed April 5, 1890.
Amplification and details of apparatus for carrying out the system shown in No. 451,239 above.

Electric Switch, H. T. Clark, 451,267. Filed Feb. 5, 1891.
A quick acting or "snap" switch.

Electric Switch, H. T. Clark, 451,268. Filed Feb, 25, 1891.
A quick acting or "snap" switch.

Solenoid and Spool Magnet, H. S. Park, 451,308. Filed March 20, 1890.
Designed to provide for increasing the extent of movement of the core of a solenoid.

Electric Switch, H. A. Chase, 451,397. Filed Nov. 2, 1886.
A switch designed for connecting instruments at a main or central office in any desired one of a number of circuits radiating from such office.

Railways and Appliances:—

Electric Railway, R. M. Hunter, 451,154. Filed Mar. 18, 1886.
An arrangement of conductors and circuits for supplying a branch line and a main line from the same source of electrical energy.

Electrically Propelled Car, R. M. Hunter, 451,155. Filed Jan. 3, 1891.
Relates to the mounting and gearing of motors. The motor is journaled upon each axle by journal-bearings rigidly secured to the field-magnets; a supporting frame is hung from the axles through the bearings of the motors and a support is provided between the frame and the motors.

Electric Signal for Railways, U. S. Jackson, 451,157. Filed June 26, 1890.
A system of signals to acquaint the engineer of a train and station officers of the position of trains upon the road.

Trolley, R. MacRae, 451,211. Filed July 24, 1890
Employs three rollers, two above the conductor and one below it.

Tension and Cut-out Device for Electric Railways, B. Jennings, 451,326. Filed Sept. 19, 1890.
Designed to secure a suitable tension of the conducting wire so as to maintain it approximately in a straight line.

Electric Railway, R. M. Hunter, 451.402. Filed Dec. 2, 1890.
Relates particularly to the position of the overhead conductor upon curves, where it deviates from a position midway between the rails to one nearer the inner rail of the curve.

Telephones and Apparatus:—

Telephone Call Box, F. Villiers-Stead and E. R. Hedgman, 451,143. Filed July 28, 1890.
A "nickel-in-the-slot" call box.

Literature.

Les Theories Modernes de l'Electricité. By Oliver J. Lodge. Translated from the English by E. Meylan, Paris, 1891. *Gauthier-Villars et Fils*, 216 pp.; 5½x9 inches. Price $1.60.

Dr. Lodge's work on Modern Views of Electricity is too well-known to require any extended notice at this time. In the version before us the translation has not only done justice to the original in accuracy, but has retained much of Dr. Lodge's happy style of expression which makes his works so readable.

OBITUARY.

JUDGE HENRY SOUTHER, who was a native of Lynn, Mass., died on April 4th, in Fredericksburg, Va., where he has resided for three years. He was 65 years of age. Judge Souther was president and treasurer of the Bridgewood Milling Co. and president of the Electric Light Co. In Erie, Pa., he served two term as corporation judge.

UNDERGROUND WIRES IN PITTSBURGH.

The question of putting the electric wires under-ground, which had been dormant in this city for a long time, writes our Pittsburgh correspondent, was again resurrected a few days ago in the Pittsburgh Council chamber. Two resolutions were offered as ordinances, and both made compulsory to telegraph, telephone and electric light companies to have their wires put underground. The first ordinance provides, that after July 1, 1891, it shall be unlawful for any telephone, telegraph or electric light company to raise, maintain, continue, use, operate or employ in that part of the city, which is known as the "city proper," any pole, overhead wire, overhead cable or device above the surface of the ground by means of which electricity is or has been transmitted, or to keep any such pole or wire now or before that date erected. Each and every pole and wire now in that portion of the city shall be taken down before that date at the cost of the owner. Any pole or poles not removed on that date shall be removed by the officers of the department of public safety, and any company interfering with the department in the removal of these poles shall be fined not less than fifty and not more than one hundred dollars.

The second ordinance relates to underground wires and provides that any company engaged in the electric light, telegraph or telephone business prior to July 1, 1891, and which has complied with the ordinance for the removal of the poles and wires shall have the right to enter on the streets for the purpose of laying the necessary conduits and subways for their wires on these conditions:—A plan of the proposed system shall be submitted to the department of public works, subject to approval before the work is begun; all wires shall be three feet below the surface and close to the curb, and not more than two feet of any street shall be open at one time; the street pavement must be replaced in good condition; the city shall have the right to use the conduits for the wires of the bureau of electricity; the system shall always be under the supervision of the department of public safety, so far as the safety of the public, police and fire apparatus are concerned; reports of the working of the system shall be furnished in detail when requested by the department of public safety. Any violation of this ordinance will be punished the same way as the one above quoted.

The fact that the wires of the electric street car companies are not mentioned at all in the ordinances has given rise to a great deal of discussion among the companies, which are interested in the ordinances. In the meantime, however, the street car companies are congratulating themselves on the favorable discrimination made by the city fathers for their particular benefit.

SAFETY INSULATED WIRE AND CABLE CO.

MR. E. T. Barberie, the electrical engineer and expert, announces that he has become associated with the Safety Insulated Wire & Cable Company of this city, having been appointed Electrical Engineer of its Underground Cable Department. The Safety company is now prepared to undertake the construction of underground electric light, electric power, telegraph and telephone conduits; to equip them with its own cables, and to guarantee the perfect practicability and permanency of its work. The admirable service rendered by this company's cables, since they were first placed underground in New York, over two years ago, has been a source of great gratification to the management and is considered to warrant it in taking this new departure. The company believes that in order to maintain the record which it has made in New York, it must permit its cables to be handled only by its own staff, and to be drawn into such conduits as shall receive the approval of its own engineers. Mr. Barberie has had an experience of many years both on submarine and underground cable construction, first while electrician of the Postal Telegraph Cable Company, and afterwards in the same capacity with the Manhattan Electric Light Company, the construction and testing of whose underground circuits he had supervision of for over a year.

TRUEX & VAIL.

Truex & Vail have moved into their new quarters in the Electrical Exchange building, and are now receiving their friends there. They will represent as before the Accumulator Co., the Electro Dynamic Co., the Walker Electric Co., and act as general sales agents for the Edco dynamos, and motors, Walker meters, switches, etc.

A. B. LAURENCE.

Mr. A. B. Laurence, New York manager for the Shultz Belting Co., of St. Louis, reports sales of the "Electric Dynamo" belt for the Columbia Building, the Central Railroad of New Jersey Building, the Inman steamer, "City of Chicago," the New Haven Steamboat Co., and the Staten Island Light, Heat and Power Co.

TRADE NOTES AND NOVELTIES

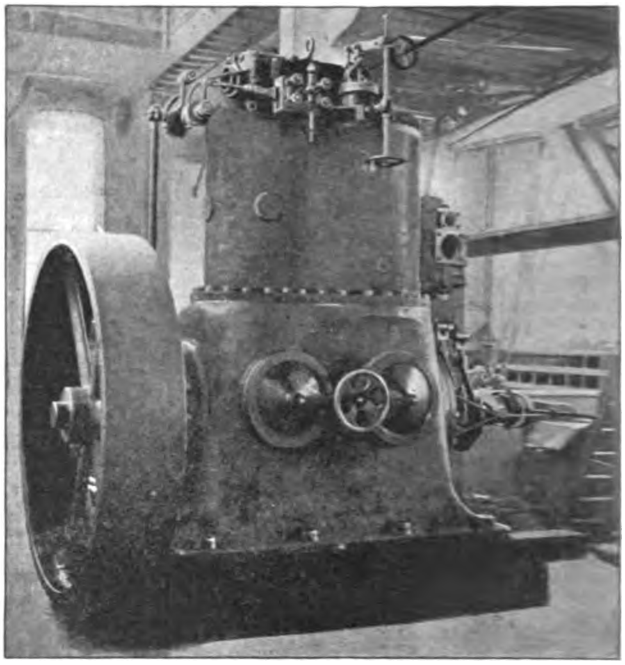
AND MECHANICAL DEPARTMENT.

Don't depend for new business on the advertising you did last year.

A NEW GAS ENGINE.

A new gas engine, designed for use in connection with electric lighting in plants where every foot of floor space is valuable, has just been completed in Pittsburgh. The inventors of this new engine are Mr. Albert Schmid, the superintendent of the Westinghouse Electric and Manufacturing Co., and Mr. Chas. Beckfield.

This is one of the largest gas engines ever constructed, that shown in the accompanying illustration being of 120 h. p. capacity, and was designed and built to take the place of the ordinary steam engine. It has the same movement as the Westinghouse automatic engines and in appearance resembles them very closely. It is claimed, however, to possess a number of advantages over the ordinary steam engine, and to have double its efficiency. It is economical, as it requires no boiler, and takes up little space, and is a great deal safer. In connection with electric lighting plants it will be of especial advantage in large cities, where ground is expensive.



THE SCHMID & BECKFIELD GAS ENGINE.

This engine can be operated with either illuminating gas, fuel gas, or natural gas. Its construction is remarkably simple and without complicated parts.

The inventors are now engaged in the organization of a company, and it is their intention to go into the manufacture of these engines immediately. A plant is to be erected in Pittsburgh as soon as possible. When the factory is in operation the inventors intend to manufacture engines from ¼ h. p. up to 200 h. p.

INTERIOR CONDUIT AND INSULATION CO.

The Interior Conduit and Insulation Company have taken possession of their new suites of offices in the Edison Building at 42 and 44 Broad street. The offices are situated on the fifth floor, fronting on Broad street and on both sides of a private hall, separated from the main passageway by an artistic gate. The several rooms are large, well ventilated, and have an abundance of light from all sides throughout the day. The two large rooms in front are occupied respectively by Mr. E. H. Johnson, president, and Mr. E. W. Little, general manager, and are furnished simply but substantially in hard wood. Mr. E. T. Greenfield, the company's electrician, has his office, draughting and show rooms directly back of Mr. Johnson's office, Mr. F. A. Mason, with the financial department, adjoining. All the conveniences usually found in a suit of well-appointed offices go to make fitting headquarters for such a progressive company.

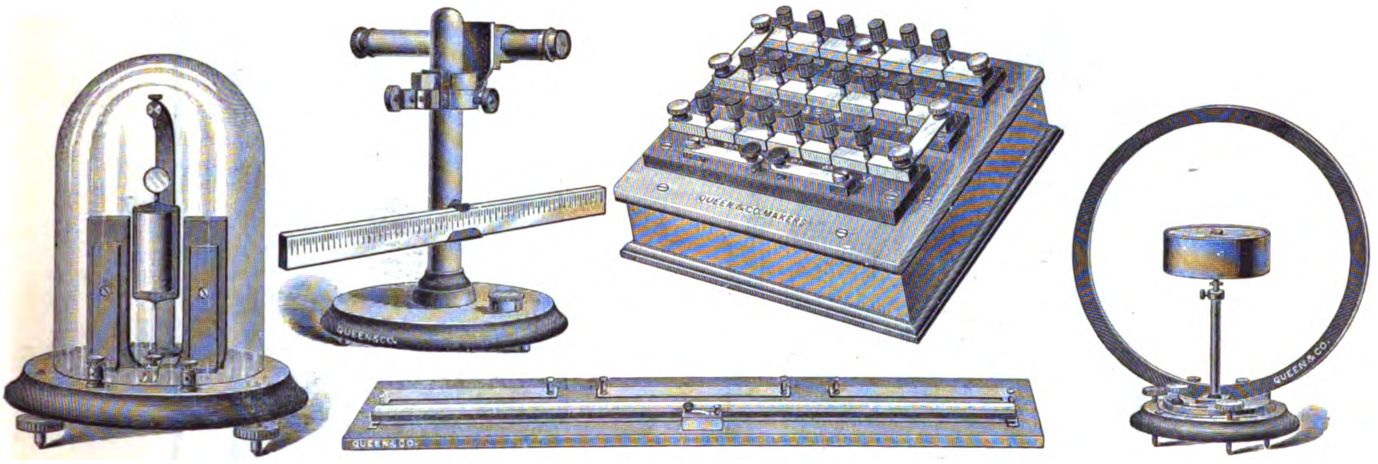
THE RUSSELL DISC ARC LAMPS.

Much time has been spent by the Russell Electric Company, in perfecting their disc arc lamp described in another page, and with the machinery now employed they are thoroughly equipped to turn out lamps with all the parts interchangeable. The factory of the company is situated at Ballardvale, Mass., and the offices at 85 Water street, Boston. Mr. A. W. Rounds is the president of the company, and Mr. F. H. Carpenter, treasurer; Mr. H. E. Chapman is in charge of the factory, and Mr. Hector Dewar is electrician .The company are now ready to supply lamps at short notice, and invite a thorough inspection of the lamp.

SCHOOL ELECTRICAL APPARATUS OF JAMES W. QUEEN & CO.

Last week we illustrated some of the new electrical apparatus of James W. Queen & Co., of Philadelphia, for schools. A few more pieces are shown herewith.

The well known Deprez-D'Arsonval Galvanometer, as it is commonly called, is shown in Fig. 1. This galvanometer, one of the most sensitive types known and very "dead beat," needs no explanation or comment. Fig. 2, is a tangent and sine galvanometer. Fig. 3, is one of the four or five resistance boxes of this series, and represents the type; the particular box shown is a combination Wheatstone bridge and resistance set, having 12 coils in the resistance portion aggregating 1,110 ohms, and bridge arms of 10, 100 and 1,000 ohms on a side, thus giving a range of measurment from $\frac{1}{100}$ ohm to 111,000 ohms; the coils in these sets are all guaranteed to $\frac{1}{8}$ of 1 per cent. A slide wire bridge is shown in Fig. 4.



QUEEN & CO.
QUEEN & CO. MAKERS
QUEEN & CO.
QUEEN & CO.

FIGS. 1, 2, 3, 4 AND 5.—NEW SCHOOL APPARATUS OF JAMES W. QUEEN & CO.

There is also a reading telescope. Fig.5, for use with the previously mentioned reflecting galvanometers. This telescope has adjustments for altitude, and both course and fine adjustments for azimuth. For those not partial to telescope methods, a neat lamp stand and scale is provided. Keys of all descriptions, some of which are illustrated, are included also. The list is completed by speed counters, standard cells, chloride of silver test batteries, small ammeters and voltments, copper voltameters, etc.

SAMSON ARC LIGHT CORD.

The cord used for hanging arc lamps is a comparatively small item in the supply account of a central station, but is quite an important one. Where serious injury to so complicated a mechanism as an arc lamp, as well as grave danger to the public is concerned, it is well to give the subject serious consideration; and from an economical standpoint as well, it is of great importance that sizes and grades of cord should be adapted to the service rendered. A cord that is overloaded will not wear nearly as long as one that is not. Solid braided cords are now coming into general use for this purpose, and the Samson cordage works of Boston, who are the pioneers in this line, have found from long experience that cotton is the most durable material for all outdoor service, and that when waterproofed this cord will outwear all others. Their process of waterproofing, besides protecting the cord from the action of the weather, prevents abrasion in running over the pulleys. The company will be glad to answer any inquiries as to sizes and grades of cord adaptable to varying circumstances.

EVANS FRICTION CONE.

The Washburn & Moen Mfg. Co., of Worcester, are to have in their immense wire factory which they are building in Chicago, one room which will contain two lines of the Evans friction cone pulleys of 75 h. p. each. Each line will contain twelve sets of 6 h. p. cones, with the driving cones coupled together, making two continuous lines of 75 h. p. each. Each set of cone pulleys gives a variation of from one to nine. The speed can be changed or any cone can be stopped while the main line is running.

"ELECTRIC POWER."

The offices of *Electric Power* have been removed from 132 Nassau street to rooms 527, 528 and 530 Electrical Exchange building, 136 Liberty street.

THE UNIVERSAL ARC LAMP COMPANY.

MR. E, S. MENDELS having resigned his position as General Manager of the above Company, Mr. F. W. McClement has been appointed as Acting General Manager until further notice.

THE FITCHBURG STEAM ENGINE CO.

The Fitchburg Steam Engine Co., Fitchburg, Mass., have just closed contract for the engines, shafting, etc., for the W. C. T. U. Temple in Chicago; are also building a large compound engine for the Arnold Print Works, North Adams; large compound for the Brattleboro (Vt.) Gas Light Co.; are shipping complete outfit, including large engine, boilers, etc., for a brass plant in Virginia; are building an engine for the morocco factory of Paschall, Lichten & Lyon, Frankford, Pa.; also large engine for Barnes & Beyer, Phila.; are putting in engine for the Tubular Rivet Co., Wollaston Hights, Mass.; are building engine for the Sockanosset School for boys, Howard, R. I.; also large engine for the Revere Rubber Co., Boston; also engine for Three Rivers Paper Co., Mich.; also large engine for Chicago, and a great many smaller ones. They have just issued a new catalogue, containing full information of our different styles of engines which they will be pleased to send upon application.

THE "CENTRAL ELECTRIC" CATALOGUE.

We had occasion recently to comment on the excellent new catalogue issued by the Central Electric Co. It has elicited some well deserved eulogiums, of which the subjoined is a sample :—

WATERLOO ELECTRIC COMPANY.

WATERLOO, IOWA, April 27, 1891.

CENTRAL ELECTRIC CO., CHICAGO.

Dear Sirs:—We are just in receipt of your new catalogue of electrical supplies. Please accept our thanks for same.

It is without doubt the finest and fullest catalogue sent out by any firm in the United States, if not in the whole world.

Hoping to be able to get even with you for kindnesses in the past, we are,

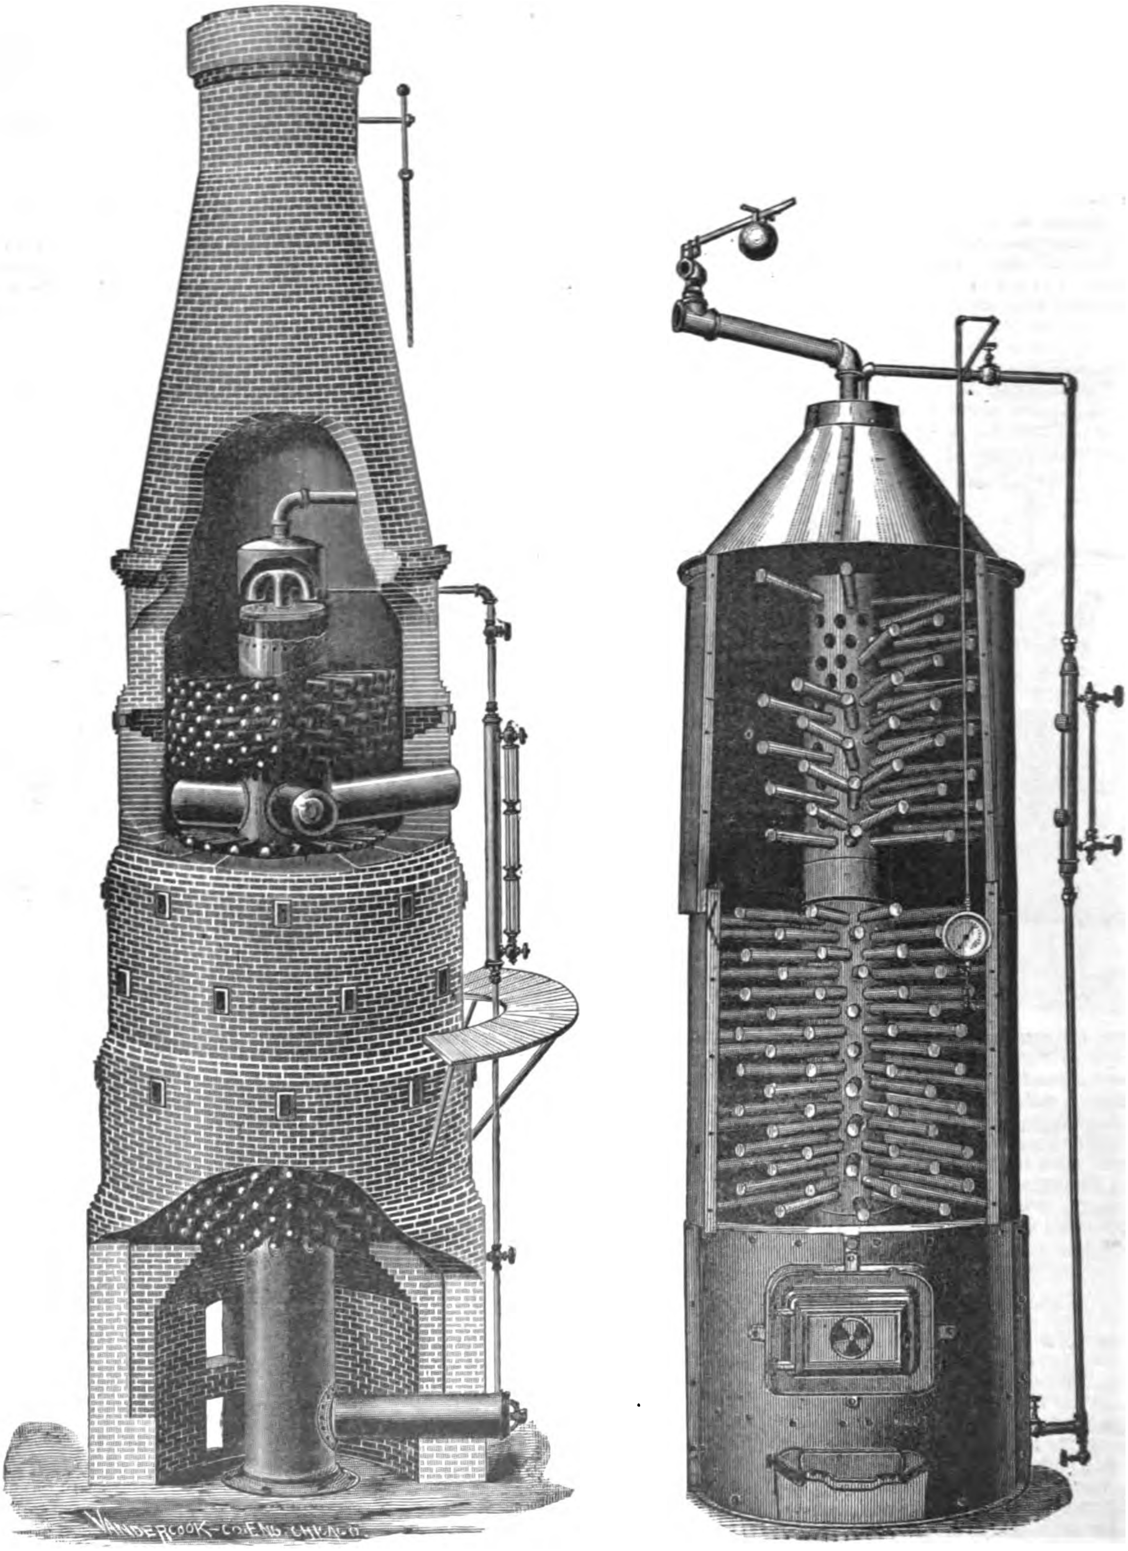
Very truly yours,

WATERLOO ELECTRIC CO

MR. J. LENLON, president of the Ravenna, O., gas and electric light company, recently died suddenly of heart trouble.

THE HAZLETON TRIPOD BOILER AND FEED-WATER PURIFIER.

The accompanying illustrations represent the Hazelton tripod boiler and purifier, manufactured and built by the Hazelton Tripod Boiler Co., 170 Twenty-second street, Chicago. Figs. 1 and 2 show the boiler. Its centre column being upright, the sediment falls to the bottom by gravity, where it is easily removed. The entire boiler acts as heating surface, and the full heat of the fuel is applied most effectually. The part of the boiler above the water line is steam space, the tubes above the water-line acting as dryers. The steam thus leaves the boiler at a higher temperature than that due to the pressure. The gain from this alone is considerable, as it admits of a shorter cut-off owing to the greater expansive power of dry steam. All parts of the boiler are easily accessible for repairs and cleaning. The ground space required is very small, a five hundred horse power boiler only occupying a circle seventeen feet in diameter, and no other stack is required than the brick work of the boiler itself. This brick work may be replaced by an iron jacket with provision for a fire-clay lining in the fire-box.



Figs. 1 and 2.—Hazleton Tripod Boiler.

These boilers are built so that they can be boxed up for mule back transportation, no box weighing more than 250 lbs., and are being extensively used in mountainous regions difficult of access, for mining and prospecting purposes. They are now in use in the Rocky Mountains, Mexico, Central and South America.

Either wood or coal can be used for fuel. These portable boilers are built in sizes from five to thirty-five horse power.

The Hazelton purifier is shown in Fig. 3. It heats the water to the same temperature as that in the boiler. With 80 pounds boiler pressure the temperature in the purifier will be 314 degrees Fahr. The temperature necessary to precipitate the lime held in solution is 302 degrees Fahr. The water inlet pipe (top cylinder) is from a heater of any kind; from this cylinder the feed water flows by gravity to the boiler, as the purifier is under boiler pressure.

The coke in the two cylinders takes up the lime and will retain 95 per cent. of all the solids held in solution.

The vacuum heater uses steam from the pumps, and only a portion of the exhaust from the engine sufficient to raise the temperature of the feed water to the boiling point. Thus the rest of the main exhaust is available for heating purposes and is valuable, being at high temperature. The steam entering the heater, being condensed, returns to the boiler pure water, amounting to about 20 per cent. of that used. The heater contains no tubes, and, it is claimed, will last 35 years.

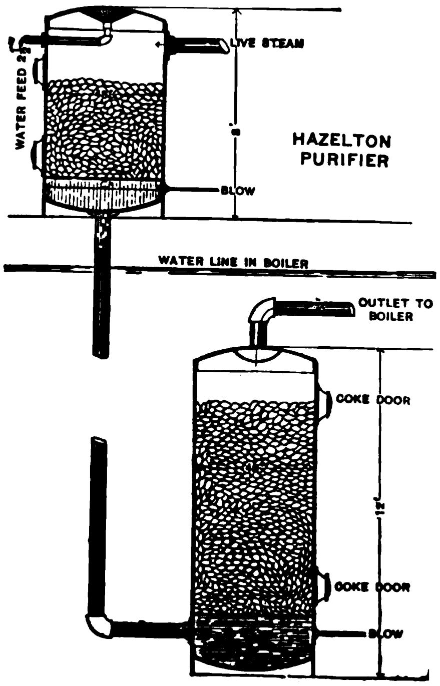


FIG. 3.—HAZLETON FEED-WATER PURIFIER.

The water enters at the top, and falling 6 to 14 feet, according to the size, through exhaust steam, is instantly heated and passes out from the lower end by gravity to the pump, and thence through the purifier to the boiler.

CHAS. A. SCHIEREN & CO.,

The following is a letter received by the above concern from The Home Electric Co., of Seattle, Wash., one of the largest companies in the Northwest:—

"We have two of your Perforated Electric Belts running, one of them has been in use about thirty days, and the other has been running two weeks; they run beautifully, and are very satisfactory. You may refer other parties to us if you choose, and rely on their receiving a very favorable impression of the value of your Perforated Belts.

Yours truly,

HOME ELECTRIC CO.

BY E. C. KILBOURNE."

THE WEEMS ELECTRIC RAILWAS SYSTEM.

The Electro-Automatic Transit Company of Baltimore, Md., has sold its right, title, and interest to the Weems Electric Railway System, a new company organized in New York to develop railroad transit by electricity. The Weems Electric Railway System has been organized with a capital of $2,500,000, divided into shares of $100 each. The officers are: O. J. Smith, president; David G. Weems, vice-president and general manager; Wayne B. Stowe, secretary; John H. Grant, treasurer; A. de R. Sappington, counsel. The general offices of the company are at 32 and 34 Vesey street, New York. The engineering department still continues at 6 South street, Baltimore, the office of the old Baltimore company, with David G. Weems in charge.

In speaking of the removal of the company to New York, Mr. Weems said it was because a larger amount of capital and a greater interest could be secured there for putting his invention into practical operation. The difficulty in Baltimore was in getting practical men to devote sufficient time to push the scheme to the conclusion desired. Those who took stock in the concern, while subscribing liberally and having faith in the ultimate success of the motor, were men whose other business interests were large, and demanded all their time. The New York company has been organized, he said, with ample working capital, and has therefore absorbed the Baltimore concern. Factories for the manufacture of the motors and the cars to be used by the new system will be erected, and the work pushed with all rapidity. It will be remembered that with the Weems system, a speed of 125 miles an hour has been reached on the experimental track at Laurel, Md.

THE NEW AMERICAN TURBINE.

AMONG the many turbine wheels now on the market, few have had as great a share of popularity as the New American, manufactured by the Dayton Globe Iron Works Co., Dayton, Ohio. The New American is not, strictly speaking, a new piece of mechanism; it is the outcome of the American which was first put on the market in 1859. It has been designed specially with a view to strength and durability and will stand the strain of any head; at Niagara Falls, the Cataract Milling Co. has a 25 foot wheel giving 525 h. p., while another one in the same neighborhood, running under 100 feet head, is giving 2,000 h. p. They run with the same steadiness under all heads, are under the greatest control, and are perfectly susceptible to the governor—points which are invaluable features of water wheels.

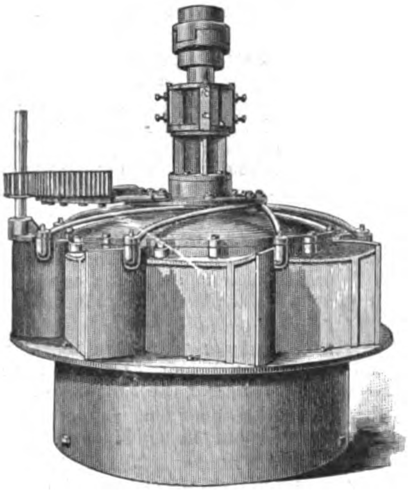

FIG. 1.—NEW AMERICAN TURBINE.

In a fully illustrated catalogue which can be had from this concern, those interested in such matters can find many full descriptions of the manufacture of the New American, its efficiency under different heads, cuts of the wheel and its various parts, of methods used in setting them, and a multitude of descriptions and prints of practical use to any one contemplating the purchase of a turbine. The volume likewise embraces many valuable tables of rules.

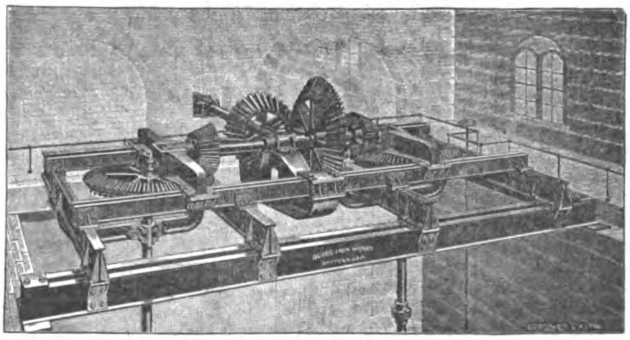

FIG. 2.—GEARING OF WATER POWER PLANT.

In the accompanying illustrations, Fig. 1, shows the wheel itself, while Fig. 2, is a view of the gearing in a large water power plant at Eau Claire, Wis. The wheel is mounted on an iron bed, and can be fitted with additional draft tube, or the inlet may be placed at any convenient angle.

THE BALL ENGINE CO.

The following important circular has been issued by the Ball Engine Co., of Erie, Pa.:

"We take pleasure in announcing to our friends that on and after May 6th, 1891, we will be represented in New York by Messrs. E. T. Copeland & Co., 106 Liberty street. Mr. Copeland's long experience in the sale of engines in New York gives us assurance that our interests will be in intelligent hands.

"We wish also to announce that, owing to the great increase of our business, we are erecting a large addition to our works, which will be equipped with special tools, ensuring perfect construction of our engines. Every engine is fully tested under steam and load before leaving the shop, and every part of the work is thoroughly inspected.

"We are prepared to furnish promptly simple, tandem compound, cross compound and triple expansion engines, up to 500 h. p."

WESTERN TRADE NOTES.

Mr. Frederick Sargent, the electrical engineer of the construction department of the World's Fair, is very busy working out the engineering details of the electrical portion of the Fair. The selection of Mr. Sargent for this position was a most excellent one, as he has had a very wide and diversified experience in electrical engineering and is one of the most capable and energetic men in the profession.

Mr. M. E. Baird, the general agent of the Eddy Electric Motor Co., was a visitor to Chicago last week.

The Knapp Electrical Works are enjoying a brisk run on their electrical supplies. Mr. Myron A. Knapp has just taken the general Western agency of the Safety Insulated Wire and Cable Company, of New York. The Safety seamless rubber wires are well-known, and in such hands the demand for them in the West will be ever on the increase.

The Northwestern Electrical Specialty Co., 1,017 Chamber of Commerce Building, Chicago, are finding a ready sale for the "Economic" incandescent lamp, for which they are the general Western agents. Mr. Geo. L. Kirkham is the manager of the company.

Mr. E. S. Bowen has just completed the work on the complete steam plant for the new south side Edison station, which Mr. Frederick Sargent is installing for the Edison Co.

The Stationary Engineer has now moved its offices to new and handsome quarters at room 24, the Mallers Building.

The Illinois Electric Material Co., 158 Fifth avenue, report their trade in the famous Bishop wires and cables to be very active and increasing largely. Canvas Jacket line wire and Electrix specialties, especially the switches and sockets, are in extensive demand. The wisdom of their recent move to larger and more commodious quarters is now clearly shown by the amount of trade done in the handsome new store, and they have done well "to get in on the ground floor." From the inquiries they have for poles and line supplies they predict a very large and extensive trade for the year, and their present orders substantiate their views.

The Sunbeam Incandescent Lamp Co. are meeting with the most signal success in the introduction of the Sunbeam lamp. Although this lamp has been on the market for but a little more than a year they estimate that there are now some 125,000 in daily use. This is a striking testimonial to the economy of the lamps and the general satisfaction that they are giving.

Mr. A. C. Robbins, well-known amongst the telegraphic fraternity in the East, who has been spending some weeks here, has left for Portland, Ore. He expresses himself as delighted with his short sojourn here, and the many courtesies extended him by the electrical people of Chicago.

"**The Gem**"—The incandescent lamp manufactured by the Thwing Electric Company, of Chicago, has been felicitously named "The Gem." This is highly appropriate and before long, no doubt, we shall see the Gems all over the country.

The Street Railway Gazette people have abandoned the offices they have so long held in the Lakeside building, and found a larger home for themselves in the Mallers building, and as of yore, Messrs. Munroe & Cavell will be found full of information and courtesy at their new quarters.

The Electrical Talent of 331 The Rookery, comprising Mr. Geo. S. Searing, of The National Electrical Mfg Company, of New York, Mr. G. A. Edward Kohler, of the Eddy Electric Motor Co., and Mr. Thos. G. Grier, of the National Engineering Bureau, having found their genius too much cabined and confined in their old quarters, have removed to larger rooms in 339-341 The Rookery.

Mr. James Mitchell, formerly chief engineer for the Pacific slope district of the Thomson-Houston railway department, has been recalled to go immediately to Brazil to install a large street railway plant there.

The Central Electric Co. report large sales on the Packard incandescent lamp. They find that the lamp is very well received by users, and is considered by everybody one of the very best incandescent lamps ever made.

The Okonite Base Ball Club, consisting of the employees of the Central Electric Co., are whitening up their belts and getting in trim for the summer's campaign. They have already secured a diamond in Jackson Park, near the World's Fair grounds, for Saturday afternoons in July and August and will then be ready to meet all comers. This club covered itself with glory in the memorable contest with the Kerite Club, and we expect to see some very brilliant work from it the coming summer with the Hittites.

Cutter's Lamp-Supporting Pulley is having a steady sale in the West, where many of the new arc light plants will use it exclusively. Others are substituting it for the covered or open pulleys now in general use. The need of both a lamp support and a sleet-proof pulley is making itself felt, hence it is not surprising that a pulley which combines these features should sell well.

NEW YORK TRADE NOTES.

Okonite.—Among the recent additions made by Mr. Richard Varley, Jr., chief electrician of the Okonite Company, in their Passaic factory, is a new Thomson quadrant electrometer. Mr. Varley is to be congratulated upon having one of the most thoroughly equipped testing laboratories in the country. Mr. Varley has recently invented a system of locating very minute faults in insulated wire. The instrument is perfectly automatic; no electrician being required to manipulate it. In the short space of 30 seconds a fault having a resistance as high as 2.5 megohms can be located to a fraction of an inch; and in many cases after a fault has been located, the imperfection in the insulation is so minute that the eye can hardly detect it.

Stanley & Hall, 32-34 Frankfort street, this city, have added to their line of electrical house fittings, speaking tubes and all apparatus for thoroughly equipping a building with this line. Their business has grown so steadily that they have found it necessary to add two floors to their old quarters. Everybody who crosses the big bridge is familiar with their modest three-story sign.

The Phœnix Glass Co., 729 Broadway, this city, have new designs in shades for electrical purposes. This company has a most complete line of this class of goods, and a purchaser who cannot find a design among their collection to please him, would be very difficult to please.

McCreary Electrical Specialty Co. have removed from 18 Cortlandt street to the Electrical Exchange Building, where Mr. McCreary will be glad to meet all his old friends and customers.

C. S. Van Nuis, of "Ajax" switch fame, has joined in the procession and removed from his old quarters at 74 Cortlandt street to the Electrical Exchange Building.

NEW ENGLAND TRADE NOTES.

The Electrical Supply Co., of Ansonia, Conn., have decided to enlarge their factory to double its present capacity. Their fine business grows remarkably, and no small portion of it is due to the brilliant success of the western branch under Mr. F. S. Terry.

The Redding Electric Co., of Boston, have made a re-appointment of their officers, and are preparing for a large increase of their business during the coming season. Mr. Harvey Redding is president of the company, James Redding general manager, H. M. Nicholls secretary, and H. P. Stanwood treasurer. Mr. Stanwood is a member of the firm of Converse, Stanwood & Company of Boston, and will use every endeavor to push the firm to the front in the general electric supply business. The company have some important specialties in watchman's time clocks and fire alarm systems, batteries, etc., and will secure new agencies for specialties.

The Wainwright Manufacturing Co., of Massachusetts, have just sold the following heaters and condensers to electric companies:—Two 120 horse-power surface condensers to the North Hudson County Railway Co., Hoboken, N. J.; one 125 horse-power feed water heater to the National Electric Light Company, Eau Claire, Wis.; one 150 horse-power feed water heater to the Pleasant Valley Coal Company, Salt Lake City, Utah for their electric plant.

☞ ***Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Miscellaneous, etc., will be found in the advertising pages.***

THE
Electrical Engineer.

VOL. XI. MAY 13, 1891. No. 158.

THE PATTEN IMPROVED ALTERNATING CURRENT MOTORS.

BY

F. Jarvis Patten.

THE writer has recently designed and put into operation with the most encouraging results, two novel types of alternating current motors, a machine of each type weighing less than 100 lbs., having developed considerably more than a horse-power without bad sparking or heating when connected in the secondary of a converter circuit.

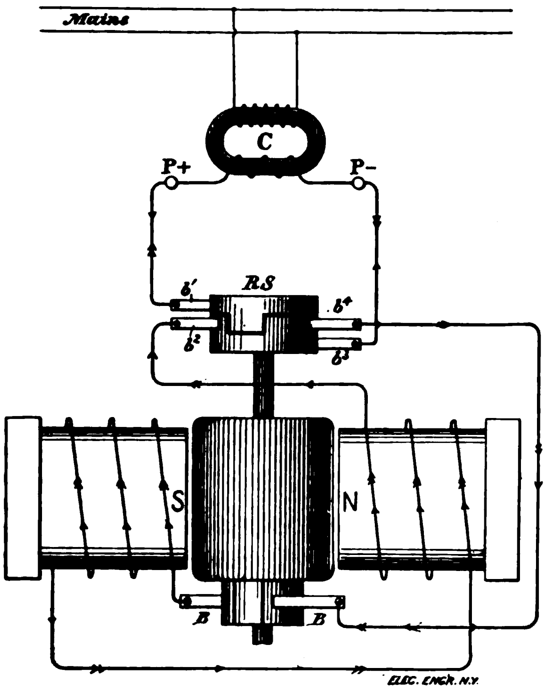

FIG. 1.—PATTEN ALTERNATING MOTOR.

In the accompanying diagrams which illustrate the two methods, the main leads of an alternating current circuit supply the converter C, and P + and P — in each figure are the terminals of the secondary circuit, to which in both cases the machine circuits are connected by means of brushes that bear upon a revolving switch R S which is carried by the armature spindle. In both methods, an ordinary direct current machine, preferably of the Gramme type is used, the windings of field and armature being modified to suit alternating current work, and the cores of both well laminated.

It is of course understood that such machines are self-starters, even when supplied with alternating currents; the fields and armatures being simultaneously reversed, the tendency to rotation is always in the same direction.

The revolving switch in Fig. 1, is composed of two continuous rings notched or halved into each other as shown. Brushes b^1 and b^3 connected to the secondary terminals P + and P —, bear upon these rings. Two other brushes b^2 and b^4, fixed in position, bear upon the middle or segmental portion of the revolving switch, and to these brushes the terminals of the machine are connected as shown.

When current is switched on, the armature begins to revolve under the action of an alternating current, the field and armature simultaneously reversing; but as the armature gains in speed, and the switch is turned faster and faster, it tends more and more to rectify the alternating current that is thus fed to the machine, until at a certain predetermined speed, which is, of course, the normal speed of the machine, and which may be either synchronous with the dynamo, or any multiple or sub-multiple thereof, the revolving switch will operate to completely rectify the current for the machine so that it will be practically fed at this speed by a pulsating direct current. Of course, at this speed the machine will give its greatest output, and there will be a tendency to hold this speed up to the maximum load; there will be no reversals of field or armature polarity, little sparking, and no appreciable heating.

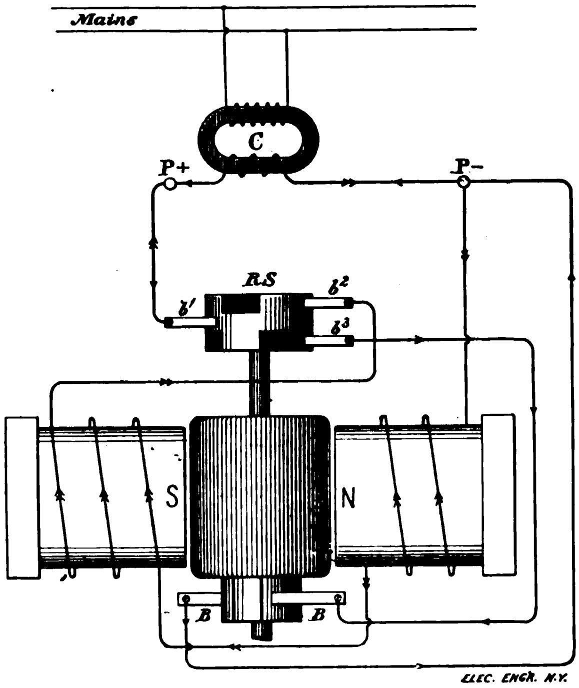

FIG. 2.—PATTEN ALTERNATING MOTOR.

Evidently the motor circuits, field and armature, may be arranged in parallel, which is the preferable way; they are shown in series merely for simplicity.

In the position of the brushes and switch shown in Fig. 1, the machine is shown taking a positive impulse of current from the left hand pole P + of the converter; evidently, if during this impulse the switch turns through the arc covered by one segment, then, when the negative impulse comes, the brush b^4 will bear on the next segment connected to the lower ring, brush b^3 and pole P —, of the secondary circuit, and current coming now from this pole will go through the machine in the same direction as before, as indicated by the double arrows.

Fig. 2 shows a different diagram of circuits by which very good results are obtained with one brush less. A different kind of switch is used, having a continuous ring at its middle portion, and alternate connected and disconnected segments on each side, arranged so that the connected segments on one side are opposite the disconnected segments on the other.

The brush b^1 bearing on the ring is connected to the pole P + of the converter secondary, and the armature of the machine is connected in a circuit from the brush b^2 to the other pole P — of the converter. The field circuit of the machine has one terminal connected to the brush b^3 and the other also to the pole P — of the converter.

The brushes b^2 and b^3 are fixed in position in such a way that one of them, say b^2, bears on a segment connected to the ring, while the other, b^3, bears on a disconnected segment. Of course, as the switch revolves, the field and armature circuits will be alternately connected in the converter circuit.

Then again there is an evident tendency to synchronism or a multiple thereof, and when this speed is reached the armature will take, say, all the positive impulses, and the field all the negative impulses of current, so that each will be supplied with an intermittent current of one direction and the polarities of armature and field will remain constant. As the impulses come to each in turn at about 115 times a second, it is sufficient to maintain a constant magnetization of both, and the machine will work as an ordinary direct current machine.

Of course, this machine, connected as shown in Fig. 2, will not start itself, because only one part, say, the armature, will receive current, while the armature stands still and its polarity will be reversing.

To make this machine self starting, both field and armature are switched temporarily into the same circuit, the machine will then start itself, and after it gets up to speed the field is switched into its proper circuit.

A CHART OF STANDARD ELECTRICAL DIAGRAMS AND SYMBOLS.

BY

Francis B. Crocker

ELECTRICAL engineers, students, draughtsmen and others engaged in electrical work frequently have occasion to make use of, or to interpret, electrical diagrams and symbols, and it is very difficult to find them when they are needed. There is also apt to be some doubt as to the correctness and authority of any particular drawing or sign. I have therefore collected the most important and standard electrical diagrams and symbols, and put them in the form of a chart for easy reference. Of course, it is impossible to make such a chart perfectly complete, but it has been attempted to represent all the most typical of the various kinds of apparatus, systems and facts which are found in electrical engineering, beginning with the simplest and passing to the more complicated.

The chart is also intended as a basis for a course of instruction in electrical draughting in technical schools and offices, there being no rules, guides or models to follow at the present time.

A few moments' inspection will enable one to find and understand any particular diagram or sign, and therefore no explanation of the chart is needed.

OIL AS AN INSULATOR FOR HIGH POTENTIALS.—III.

BY

Daniel Brooks

IN nearly all the text books published up to within a few years, oils were put down as conductors, and John T. Sprague in his edition of 1884, classes them as conductors "in the order of their specific gravity."

My first patent for the use of oil was issued in December, 1878. About that time, I stretched a mile of wire insulated with oil in the yard of my factory; the oil was placed in the glass bottles of my insulators, turned upside down and protected by a cover from rain drops. I could get no current with a battery of 200 cells during rain, between the wire and the earth, a distance, say, of 10 feet; but in a clear warm day a slight deflection was obtained, because all insulating substances show conduction as the temperature is raised; more than 10 times as much when the temperature is at 100° Fahrenheit, than at 32°.

Now we have to consider the conductivity of air as compared with other insulators when higher voltages are used. Mr. C. E. L. Brown states that "for conveying extremely high tension current, only the overhead system can be practically considered, and it is possible to construct an overhead line in such a manner that even with the highest voltages there will be practically no leakage." Perhaps in time he may think otherwise. Mr. August Schneller, of The Hague, Holland, states that he considers the transmission of high tension currents between Lauffen and Frankfort a "technical impossibility." He speaks of a tension of 30,000 volts. In THE ELECTRICAL ENGINEER of April 15th, Mr. Charles Steinmetz, criticizes Mr. Schneller's article with some very sensible suggestions.

Now, going back to the "Electrical Pousse-Café" experiment, last June it was performed at Gloucester, N. J., and, instead of using a small wire immersed in a glass jar of oil, we used two No. 0 conductors drawn into 20 feet of iron pipe. There were about 21 feet of each of the conductors twisted together, and the pipe filled with oil. The conductors were so covered with cotton as to be separated three-eighths of an inch. We tried to puncture the insulation with a Holtz machine, using two leads of rubber-covered wire, each six feet in length. The machine by itself would spark five inches, but when the poles were connected to the two conductors, they would spark only about an inch between the two spheres, the tension being so much reduced by leakage. There was brush discharge between the two rubber-covered wires, and thin blue sparks passed through the dielectric without destroying it. I refer to the rubber-covered leads which were separated from each other about six inches.

To obviate this leakage or brush discharge, I procured two glass tubes six feet in length, and drew the rubber-covered wires into them. By this means we increased the spark between the two spheres to three inches.

Now we have some idea of the difference between the air and other insulators when currents of high potentials are used, as compared with oil. If it means anything, it is, that high potential currents cannot be insulated by the air, but must be insulated with oil and placed underground. *Nous verrons!*

On the evening of May 5th, we had the Holtz machine in good condition at the Franklin Institute; it sparked seven inches between the spheres, and was witnessed by 48 members of the Electrical section. We had three jars of the Electrical Pousse-Café pattern, and sparked through the glass tubes of two of them without puncturing the insulation from wire to wire, where they were twisted together in the oil. The third one stood the strain while the spark was going a distance of five and a half inches, as measured by the president of the section, Prof. E. J. Houston.

THE ELECTRICAL ENGINEER, N. Y.

THE DIRECT ELECTRIC CO.'S STORAGE BATTERY TRACTION SYSTEM.

WHILE, as yet, the number of street cars operated by storage batteries is but small in comparison with the large number run by the overhead trolley system, indications are not wanting to show that steady progress is being made in the former method, and it is but a question of time, and probably a short time at that, when storage traction will command the serious attention of many who now look upon it as unworthy of serious consideration. It will be conceded at once that if a battery can be provided, capable of withstanding, first, the heavy usage of street railway work, without deterioriation for a long period of time, and, secondly, of a lightness such that its own weight forms but a small fraction of the total weight of the car when loaded, storage traction will at once be placed on a practical commercial basis.

With these conditions placed before them, Messrs. Montgomery Waddell, Justus B. Entz, T. H. Foote, and W. A. Phillips have worked out a system of storage battery traction which deserves attention on account of several novel features which have been practically embodied in a car now in operation on the Lehigh Avenue Railroad in Philadelphia.

The equipment and performance of this car, which is illustrated in perspective in the accompanying engraving, Fig. 1, may best be described by reference, first, to the type of battery employed.

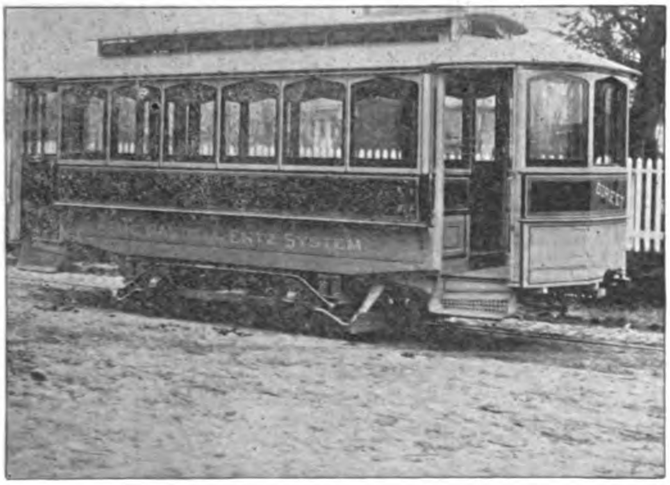

FIG. 1.—STORAGE BATTERY CAR OF THE DIRECT ELECTRIC CO.

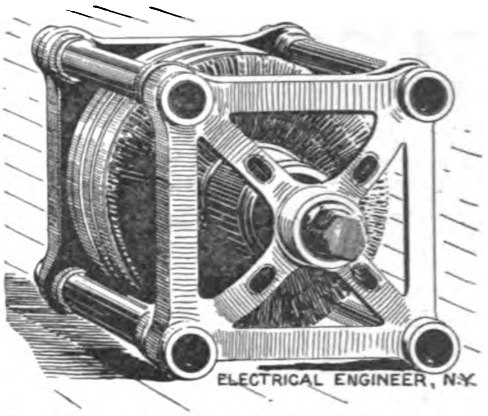
The car, which has a vestibule at either end, for the motorman, is equipped with 100 cells, each weighing 30 pounds, and therefore weighing 3,000 pounds in all. Each cell occupies a space of 5 × 7 × 12 inches, and has a capacity of 800 ampere hours. The E. M. F. of the cell on open circuit is .9 volt, and on heavy work 0.8 volt.

The cell employed is of the alkaline zincate type and consists of eight negative and eight positive plates, placed in an iron containing cell. The copper positives are built up of convolutions consisting of a central core of copper wire surrounded by, and intimately connected with, the active material, consisting of a highly porous copper mass. The inventors claim to have overcome all troubles that have arisen in this type of cell due to loss by leakage and increase of internal resistance, and that the battery will remain charged for 3 months with a loss of only 3 per cent. of its charge. A number of cells that have been in use for over a year are apparently as good as new, though they have been short circuited repeatedly, and current taken from them at the rate of 1,000 amperes until entirely discharged.

The efficiency of the cell on heavy rates of discharge, such as it is subjected to in street car work, is 80 per cent., this being the difference in voltage on charge and discharge. The ampere hour efficiency is claimed to be practically not less than 100 per cent. This is due to the fact that no gas is given off either on charge or discharge, no matter what the rate. The cell has copper insulated cables with regular brass terminals, as there are no fumes; hence no corrosion of metal parts takes place. As a consequence also, there is no trouble due to contacts or terminals burning off.

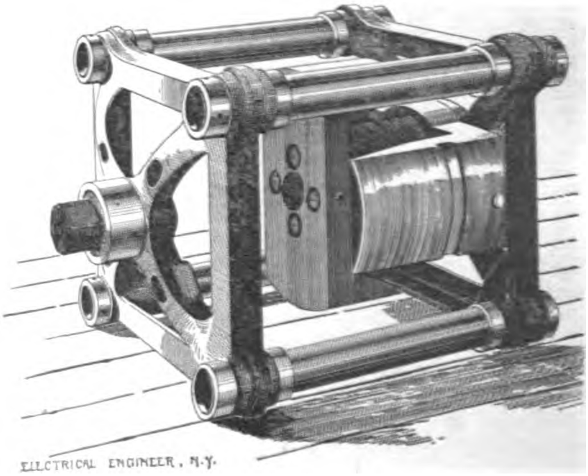


ELECTRICAL ENGINEER, N.Y.

FIG. 2.—THE DIRECT ELECTRIC COMPANY'S SINGLE REDUCTION STREET CAR MOTOR.

We now come to the motor with which the car is equipped, and to the peculiar and excellent qualities of which not a little of the success of the car is due. The motor which transmits its power to the car axle, with only a single reduction of speed, is of the 4-pole type and is shown in Fig. 2, while Fig. 3 shows the construction of the field magnets. These, as will be seen, are energized by a single magnetizing coil, and have pole-pieces bent back upon the coil. The cast iron end frames are rigidly united by four thick brass tubes, and Figs. 4 and 5 show the method of connection of the motor to the car axle.

The armature is a Gramme ring, and the magnets being on the inside, and requiring but a single coil, require the employment of but a small amount of copper and allow of a high efficiency being attained. Thus the wire on the field and armature weighs only 130 lbs. for a motor developing 20 h. p. The motor runs very cool and without sparking, even when the motor is reversed and the car stopped in its own length. The machine can also be changed from a motor to a dynamo by a turn of the switch, without showing perceptible sparking at the brushes. The motor weighs 1,200 lbs.



ELECTRICAL ENGINEER, N.Y.

FIG. 3.—FIELD MAGNETS OF STREET CAR MOTOR.

Recognizing the necessity of having a high efficiency over the large range of loads to which a street car motor is subjected, the motor has been designed with special reference to this point.

The armature resistance is .035 ohm, and the following are the losses by actual test:

Loss in Hysteresis	200	watts.
Loss in Foucault currents	120	"
Bearings and brush friction, and short circuited coil	180	"
Loss in field coil	200	"
Total constant loss	700	"

The small losses account for the high efficiency at small loads, as they are practically as high at no load, when the machine is running free, as at full load. The losses in bearings and short circuited armature coils increase slightly with load, but as they were measured when the motor was delivering 12 h. p. they are assumed to be constant for all loads. The loss due to the resistance of armature increases as the square of the load and so, of course, becomes a higher percentage with an increase of load .The point at which the armature loss due to C^2R equals the constant losses is the point of highest efficiency of the motor; this is at 14 h. p. where the efficiency is 88.5 per cent. commercial.

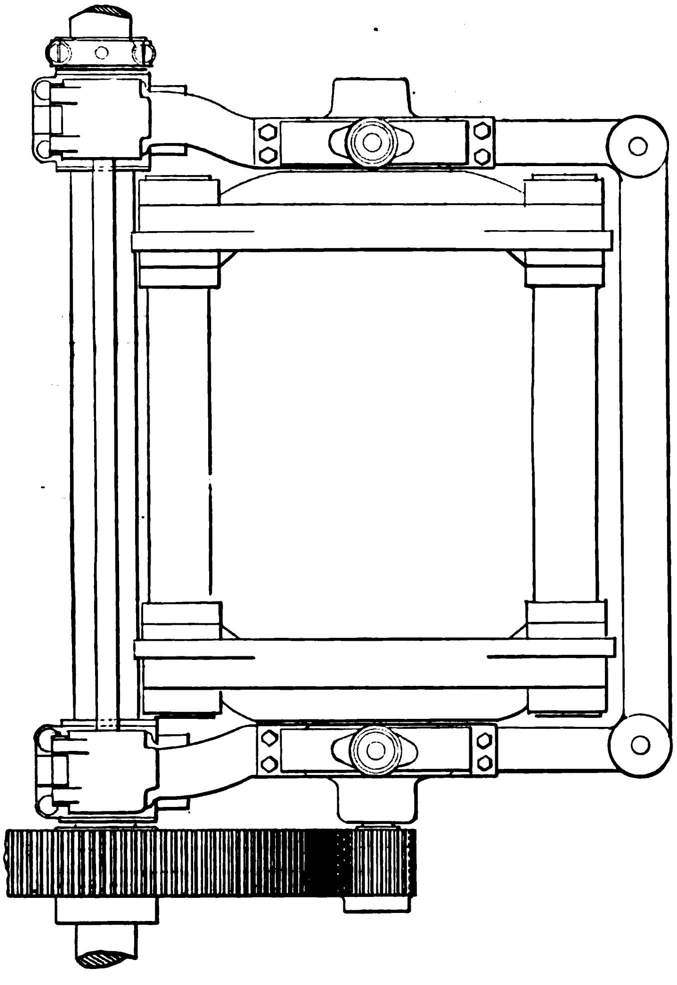


FIG. 4.—MOTOR FRAME AND GEAR.—PLAN.

The following table shows the commercial efficiency from 4 h. p. to 25 h. p.

4	h. p.	to	80	per cent. eff.
6	"	"	84	"
8	"	"	86.7	"
10	"	"	87.9	"
12	"	"	88	"
15	"	"	88	"
20	"	"	87.8	"
25	"	"	86.5	"

The average efficiency of the motor for the range of loads at which it runs is 86 per cent.; hence, with the batteries at 80 per cent. efficiency, this gives an efficiency from dynamo terminals to car axle of 86x.80 = 68.8 per cent., which is very high for traction work.

One of the most striking features of the car is the method for controlling its speed. This is done by means of a controller at each end of the platform which gives the car five speeds ahead and one back. The first 3 steps in the controller arrange the cells in different groups of series and multiple. The last two steps weaken the motor field. The reverse step reverses the car at its lowest speed.

By a combination of battery and field circuits, a constant field is kept on the motor, regardless of the amount or direction of the armature current. This enables the motor to be used as a dynamo and store back energy in the battery when stopping and going down grades, and prevents the car running away. So well does this arrangement fulfil its object that on a trip made by the writer the car was stopped in its own length when going at a speed of 12 miles per hour, and without jar. The car also ran down a 5.5 per cent. grade without using brakes, and without accellerating its speed in the least. Indeed, during the whole run up and down grades, and in starting and stopping, the brakes were not used once. This method of controlling the cars must add greatly to the efficiency of the system, as considerable power is stored in going down hill and when stopping the car. It also adds much to the safety of the system as the car can be stopped very much more quickly than with brakes, and the motor-man has only his controller to attend to, in order to have the car under complete control. Ordinarily, as is well-known, the current has first to be shut off from the motor and then the brakes applied.

The curve, Fig. 6, shows readings taken on a run with about 15 persons on board, and shows the considerable amount of power restored to the batteries in the form of current on down grades, and on slowing down or stopping the car. The amount of current taken from the cells was but 15.5 ampere hours for the out trip, as shown on the curve, and 30.3 amperes on the return trip, it being then mostly up grade work; the length of trip was just over 3 miles each way making a total of 45.8 ampere hours for the six mile run. The energy required to recharge the battery

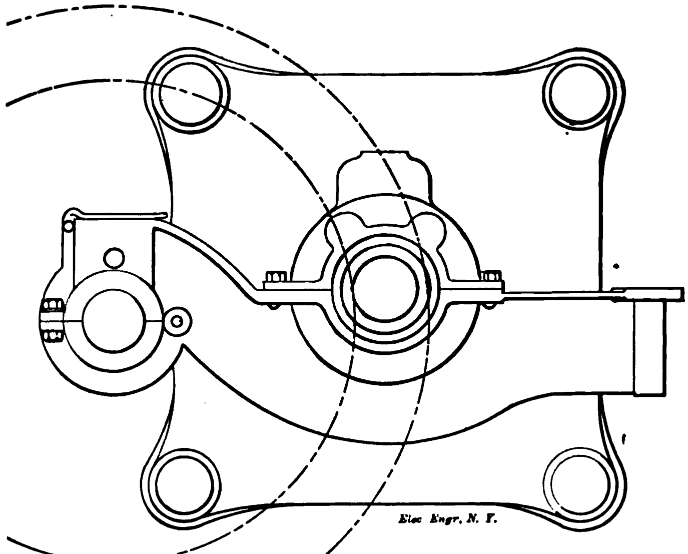

FIG. 5.—MOTOR FRAME AND GEAR.—SIDE VIEW.

for this run at the dynamo terminals would be 96 volts and 45.8 ampere hours = 4,400 watt hours = 5.9 e. h. p. hours, or 1 e. h. p. hour per car mile at the dynamo over a road full of severe curves and grades.

The car on a recent trip made the trip of 3 miles in 16.5 minutes with full load, and was then not going at full speed. The speed on a level is 13 miles per hour.

We may add that the car we have just described has been equipped by the Direct Electric Company, of this city, with the object of demonstrating the thorough practicability of storage battery traction, and they even hint at its application to heavy trains running at very high speeds. The car is being operated under the management of Messrs. Wright & Starr, electrical engineers, of Philadelphia, the company's agents in that district.

HYDROCHLORIC ACID IN BICHROMATE BATTERIES.

BY

Chas. Steinmetz.

I HAVE read with some interest, in the last issue of THE ELECTRICAL ENGINEER, Mr. Reed's remarks on the reactions which take place when hydrochloric acid is added to a bichromate cell; but I cannot quite agree with him, and for these reasons.

The chemical reaction which he alludes to,

$$Cr_2\,O_7\,K_2 + 14\,H_2\,Cl = Cr_2\,Cl_6 + 2\,K\,Cl + 3\,Cl_2 + 7\,O\,H_2$$

takes place only when bichromate is heated with concentrated hydrochloric acid, but *not* in a cold, dilute solution. Hence no free chlorine is present in the hydrochloric acid bichromate cell.

I am sorry that I have at present neither time nor facilities to determine by chemical analysis the exact composition of such a solution; but that no perceptible amount of free chlorine can be present is proven best by the entire absence of the penetrating, suffocating, and certainly characteristic smell of free chlorine. Besides this, the solution has no bleaching power, as a solution of free chlorine has, and acts upon organic matter—for instance, upon the cork of the bottle in which it is kept—in the same manner as strong acid, but not at all in the manner free chlorine destroys organic matter. If the chemical reaction should follow the above mentioned law, the amount of chlor developed would be so large that evolution of gaseous chlorine must be expected.

I did not investigate this phenomenon any farther, but I considered the advantage gained by the partial substitution of hydrochloric acid as a purely physical phenomenon due to the chlorides being generally more soluble than the sulphates, which difference of behavior is particularly great in the case of the two salts $Cr_2\,Cl_6$ and $S_2\,O_8\,Cr\,K$. In other words, $Cr_2\,Cl_6$ has very little tendency to crystallize, while $S_2\,O_8\,Cr\,K$ crystallizes very easily. Besides, the weaker chemical affinity of hydrochloric acid, which attacks the zinc less, furnishes another partial explanation of the resulting improvement.

Free chlorine is certainly a more powerful depolarizer than chromic acid, and, even if the reaction mentioned above should occur, we would not lose in depolarizing capacity, but would gain in intensity of depolarization. Free chlorine has, therefore, more than once been proposed as a depolarizer, but never found very extensive application, because of its many disagreeable properties, which make it worse even than fuming nitric acid. But in the hydrochloric acid bichromate battery it is not present in any perceptible amount.

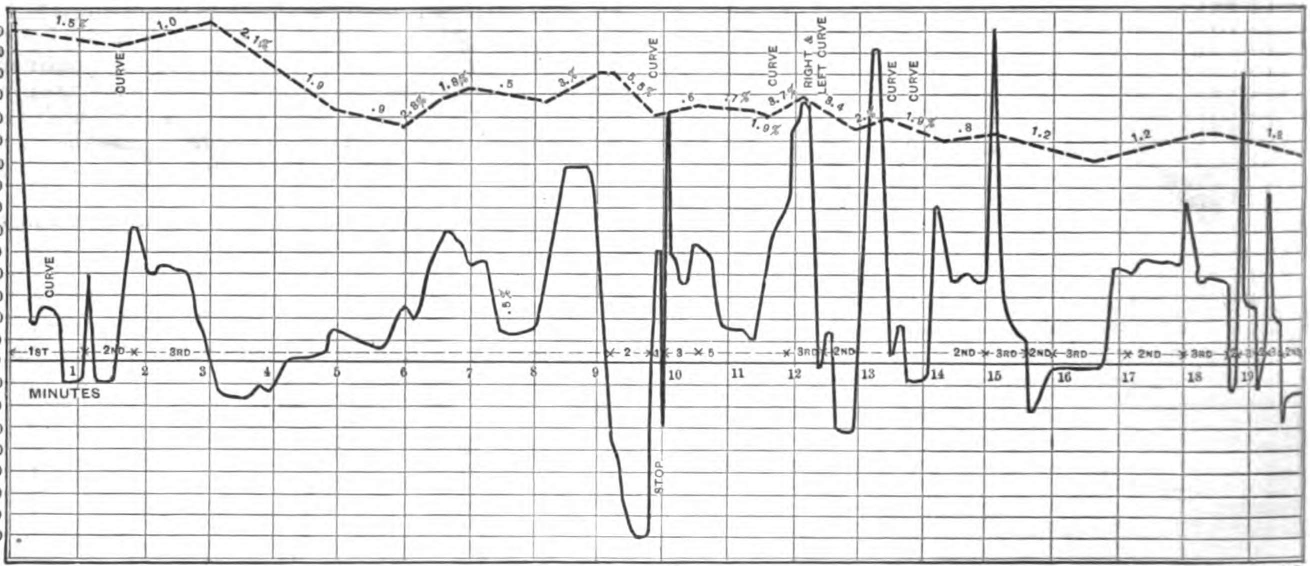

FIG. 6.—READINGS TAKEN ON A RUN WITH THE DIRECT CO'S CAR.

THE JAMES ACCUMULATOR.

IN this accumulator the positive plates consist of lead alloyed with 1 per cent. of cadmium, while the negative consist of 2 per cent. of antimony. The plates are pierced with circular holes, in which the active material is placed. Those on the positive plates are filled with a mixture of 8.5 parts of minium, 1 part of litharge, .4 parts of carded asbestos, and .1 part of powdered carbon. The holes in the negative plates are filled with a mixture of 9.4 parts of litharge, .1 part of sulphur, with .4 part of asbestos, and .1 part of powdered carbon.

UTILIZATION OF THE WATER-POWER OF THE RHONE.

As is well-known, the water-power of the Rhone is being largely utilized for industrial purposes in the neighborhood of Geneva. Col. Turettini (chief engineer of the St. Gotthard Tunnel), who carried out the works, has just issued a report as to the state of the work. The canal on the left bank is provided with 20 turbines, working up to 4,400 h. p., of which only half is at present in use. During the past year 216 motors, totaling 1,565 h. p., have been driven from the works. The smallest, of $\frac{1}{8}$ h. p., have been used to run sewing machines, while the largest (625 h. p.) has driven the electric light installation for the town of Geneva. The total cost of the works was $1,136,000., and the year's receipts reached $413,000.

CENTRAL STATION MANAGEMENT AND FINANCE.—IV.

BY

Horatio A. Foster

Form No. 4A is a general complaint card and is used for recording any trouble of which notice is sent in by customers by telephone or messenger, the proper word being crossed off to leave the other. These complaint cards are placed on a convenient hook where the inspectors can find them the first thing on entering the station. The inspectors must attend to them at once. When remedied and signed, they are turned into the office and filed in their proper place for further reference. It is certain that they will be needed many times to settle disputed bills.

FORM 4A.—GENERAL COMPLAINT CARD.

Incandescent and motor circuits are generally run from buss bars, as in the direct current systems, or are switched from machine to machine when the indicators show increase or decrease of load, as in the alternating system. Therefore it is quite unnecessary to post any card showing layout of circuits on the switchboard. In arc lighting, however, it is different, and for stations having a number of dynamos it is quite essential that some special schedule of circuits be posted to enable the switchboard tender to arrange the circuits and machines to the best advantage. Form No. 7A is advanced for this and covers about all the points necessary to know as to what dynamos to use for the circuits and when to start and stop the same. This sheet is compiled from the circuit register, form No. 23, which is made up by the superintendent or superintendent of construction from reports of work done during the day, showing both construction of line and installation of new lamps.

FORM 7A.—ARRANGEMENT OF CIRCUITS AND DYNAMOS.

By the use of both of the above forms, viz., 7A and 23, form 7, the Daily Lamp Record, is filled out by the dynamo engineer. The object of this last report is to give the exact number of equivalent arc lamps burned during the 24 hours by arc lamps, and such other installation as are usually allied with them, such as series incandescents and arc or constant current motors.

This blank will be found of great convenience in figuring costs and together with form No. 8, the Ampere Report, gives the proportions and amount of output on which are based the calculations of all costs. Of course the report of ampere hours has to be reduced to its equiva-

lent of arc lamps, of the c. p. used in the special station. This is easily done by a comparison of watts consumed by both arc and incandescents, which will give the proper basis for reduction. In figuring many hundreds of ampere reports for alternating circuits, the writer has found the following simple rule of great use in expediting calculation :—Where alternating currents of 1,000 volts are used and the lamps are 50 volts or the factor of reduction is 20, the readings being taken every half hour, by adding a cipher to the footing of the column of readings you have the lamp or ampere hours without any calculation whatever. For example, suppose the half hour readings are 12 and the total amount is 534, by adding a cipher it becomes 5,340 lamp hours at once. The following is the explanation :—534÷12 the number of readings gives us 44.5 as the average reading, and multiplied by 6 the number of hours makes 267 total ampere hours in the primary circuit; 20 lamps go to the ampere; therefore we multiply by that figure, which gives 5,340 (or the same result as above). If officials wish to go still further into detail, these ampere readings can be plotted on a cross-section card, thus giving a very handy curve or load diagram which is exceedingly useful in showing to the eye at once any faults with the circuits or stoppages, and how the business is running in general.

FORM 8.—AMPERE RECORD.

THE WASHBURN SECONDARY BATTERY.

AMONG the greatest difficulties in the way of the general adoption of storage batteries, and especially in railway work, has been the dropping out of the active material and the buckling of the plates. To overcome these disadvantages, Mr. George A. Washburn, of the Ford & Washburn Electric Co., of Cleveland, O., has devised a novel form of secondary battery shown in the accompanying illustrations. The battery embodies in its construction a porous pot which is employed to separate the positive and negative elements of the cell, as well as for holding the active material. As will be seen, Fig. 1 is a plan view, and Fig. 2 is a perspective view of the cell with one side and end removed showing the internal construction.

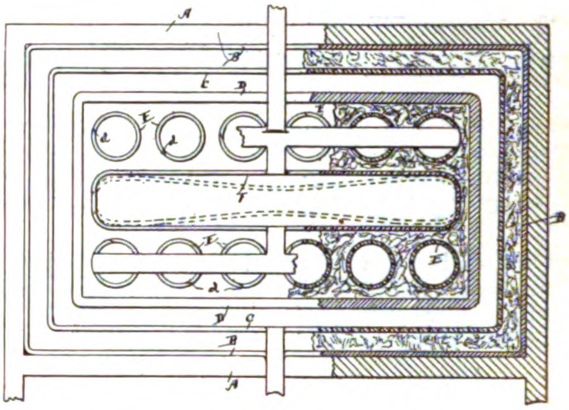

FIG. 1.—THE WASHBURN STORAGE BATTERY.

The cell consists in an outside containing vessel A, a cup B of lead forming a lining for the receptacle, and an inner perforated conducting-plate C, set at a distance from the cup B, so that active material may be placed between the cup and plate.

The porous cup D contains a series of conducting tubes E open at top and bottom, and also an inside perforated tube F, open at both ends and oblong in cross section, so as to have flat sides opposite the tubes E.

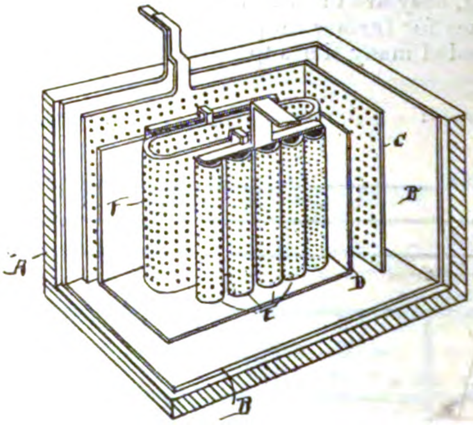

FIG. 2.—THE WASHBURN STORAGE BATTERY.

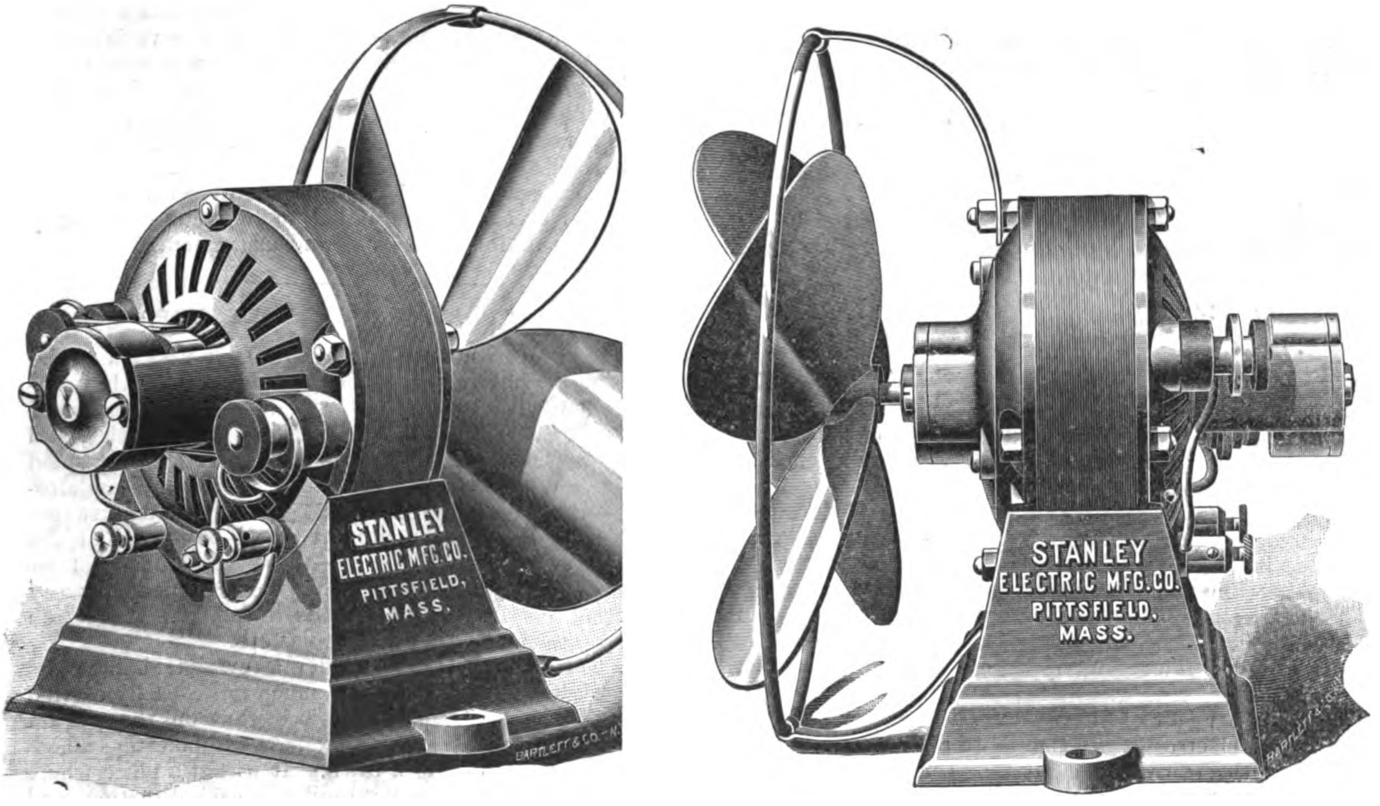
The positive electrode is arranged within the porous cup and, inasmuch as there is a tendency in the positive electrode to expand more or less, the conducting plates are so constructed that they will accommodate themselves to whatever expansion may occur, and thus save the cup. This is accomplished by making either the inside tube F alone in such a form that it will accommodate the lateral pressure exerted by the material in expansion, or by making the tubes E take up the expansion, or by constructing both with a view to the same result.

The active material is placed between the tubes E and the cup D and the central tube F, while the tubes themselves are filled with liquid. These tubes are liberally perforated, as shown in Fig. 2, so that there is the utmost exposure of the active material to the liquid, and that freedom of circulation through the cell which is necessary to the perfect working and highest efficiency of the battery.

THE STANLEY ALTERNATING FAN MOTOR.

As our readers are aware, Mr. Wm. Stanley, Jr., whose name is so intimately connected with alternating current work in this country, has recently begun the design of a number of specialties for the Stanley Electric Manufacturing Co., of Pittsfield, Mass., and as the first of these we recently described an improved transformer [1]. We are now able to present to our readers his alternating fan outfit which we illustrate in the accompanying engravings.



FIGS. 1 AND 2.—STANLEY ALTERNATING CURRENT FAN MOTOR.

The base of the motor occupies a space $3\frac{1}{2}$ x $5\frac{3}{4}$ inches, and the fan is $6\frac{1}{2}$ inches in diameter. The motor requires $1\frac{1}{2}$ ampere, but a trifle more current than a 16 c. p. lamp. The commutator is large, and the brush holder is permanent in adjustment, and the efficiency of the machine is said to be very high for a motor of this size. By providing self oiling bearings the care of the motor is reduced to a minimum, so that it needs no attention for weeks at a time. The motor has been designed specially for desk use, and to that end the fan gives a current which, while affording a cooling breeze, is not so strong as to blow about papers or subject the occupant of the room to the risk of catching cold.

MR. FRED H. ENGELL who has been in the employ of E. M. Carhart & Company, Providence, R. I., until recently, has severed his connection with that house.

EXPERIMENTS ON THE RATIO OF ELECTROSTATIC TO ELECTROMAGNETIC INDUCTIVE DISTURBANCE BETWEEN NEIGHBORING TELEPHONE CIRCUITS.—II.

A. E. Kennelly.

We may now check the previous results by calculation. The check can only be a rough one because we shall have to assume that the periodic variation of E. M. F. is a simple harmonic function of time, and that the inductance of the dynamo armature is negligible.

Let e, be the E. M. F. generated by the dynamo at any instant.

K, the mutual electrostatic capacity of the two circuits.

M, the mutual electromagnetic capacity of the two circuits.

p, the pulsation of the periodic variation of E. M. F. $(2\,\pi\, n)\ n = 1257$.

γ_c, the current in the secondary circuit at any instant in Fig. 2.

γ_m, the current in the secondary circuit at any instant in Fig. 3.

ω_1, the impedance of the primary circuit.

ω_2, the impedance of the secondary circuit.

r_2, the resistance of the secondary circuit.

All expressed in A. E. M. U.

Then in Fig. 2, if no resistance existed in the secondary path to ground, we should have

$$\gamma_c = -K\frac{d\,e}{d\,t} = -p\,K\,E\cos pt \qquad (1)$$

where E is the maximum $\pm$ periodic variation of e; but with resistance r_2 inserted as shown, the current becomes very nearly

$$\gamma_c = -\frac{E}{r_2}\cos pt \qquad (2)$$

---

[1] THE ELECTRICAL ENGINEER. April 8th, 1891.

In the case represented by Fig. 3, we have

$$\gamma_m = -\frac{d\,e}{d\,t}\,\frac{M}{\omega_1\,\omega_2} = -\frac{M\,p\,E\cos pt}{\omega_1\,\omega_2} \qquad - \quad - \qquad (3)$$

and $$\frac{\gamma_e}{\gamma_m} = \frac{\omega_1\,\omega_2}{M\,p\,r_2} \qquad - \quad - \quad - \quad - \quad - \qquad (4)$$

Also since γ_e was adjusted to estimated equality with γ_m, we should have

$$\omega_1\,\omega_2 = M\,p\,r_2 \qquad - \quad - \quad - \quad - \quad - \quad - \qquad (5)$$

where $\omega_1\,\omega_2$ was 1.9×10^{25}
r_2 " 7×10^{15}
p " 7.9×10^3

and M calculated for two circuits forming a rectangle of 12,000 × 3,000 cms. is nearly 2.0×10^5

$$\therefore\ M\,p\,r_2 = 1.1 \times 10^{25}$$

The two members of equation (5) were thus experimentally of the same order although the agreement is by no means close.

It may be fairly concluded that when two insulated wires run parallel and close together, a periodic E. M. F. acting on the circuit of one is liable to induce disturbances in the other, of which the greater part will be due to electrostatic effect, unless the product $\omega_1\,\omega_2$ is less than the ratio of their electromagnetic to their electrostatic mutual capacity.

For parallel copper wires suspended at the same height above ground, and both using ground return circuit, this ratio is, in A. E. M. measure,

$$\frac{M}{K} = 3.6\left\{\left(\log_e \frac{2h}{r}\right)^2 - \left(\log_e \sqrt{1 \times \frac{4h^2}{d^2}}\right)^2\right\} \times 10^{21};(6)$$

where r, the radius of each of the wires (in cms.).
" d, is the distance between their axes (in cms.).
" h, is their common elevation above ground (cms.).

This ratio increases with the intervening distance d, so that the closer the wires, the greater the electrostatic effect. The maximum value the ratio can attain under practical conditions is about 5×10^{23}, so that the product of the impedance in ohms of the primary and secondary circuits should not exceed 500,000 if magnetic induction is to be in the ascendant. Thus, if the primary circuit has 1,000 ohms impedance, the secondary should not have more than 500 ohms.

The particular pair of circuits experimented with in this case, favored electrostatic action more than would be usually the practice of overhead circuits, for the ratio M/K was only 2.67×10^{21}, making the limiting ohmic product of the two circuits 2,670 ohms, while M/K is commonly about 2×10^{23} for a pair of pole lines, increasing the range of the ohmic product to 200,000. It is also to be observed that when the impedance in the primary circuit is small, and especially when it is situated at the transmitting end of the line, the variation of electrostatic potential, and consequently induction, will be greatly reduced, and the above rules for estimating the proportion of static and magnetic disturbance only approximate the truth when the impedance of the primary circuit is large, and particularly when situated at the receiving end of the line.

As the lengths of the circuits increase, the greater will be the electrostatic share of disturbance, all other conditions remaining constant.

It is remarkable how small a mutual electrostatic capacity suffices to establish audible telephonic inductive disturbance of static nature, between two conductors. In fact, when the resistance to ground of the secondary circuit happens to be very high, the disturbance due to a small mutual static capacity would be hardly, and often inappreciably, increased, if the two circuits were connected metallically. For with the connections of Fig. 2,

$$\gamma_e = \frac{K\,\dfrac{d\,e}{d\,t}}{\sqrt{1 + p^2\,k^2\,r_2^{\,2}}} \qquad - \quad - \quad - \qquad (7)$$

and when r_2 is more than ten times $1/p\,k$ this becomes very nearly

$$\gamma_e = \frac{p\,k\,E\cos pt}{p\,k\,r_2} = \frac{E\sin\left(pt + \dfrac{\pi}{2}\right)}{r_2}, \qquad - \quad - \qquad (8)$$

and this is the strength of current that would be set up in the secondary circuit if the E. M. F. acted upon it directly.

As an instance of this, it was found that if the dynamo above mentioned were connected directly with the telephone through a condenser of 0.001 microfarad, and a resistance of 2.5 megohms in simple series, the clearly audible dynamo note was not appreciably strengthened by short-circuiting the condenser. In fact, substituting these values in the last equation with 7.9×10^3 for p, the ratio of the current without condenser to that with condenser in circuit is 1.0015 on the assumption of a pure sine variation of E. M. F. The same result should have followed with a condenser of only 0.00016 microfarad, allowing a ratio of 1.05 between the two currents as the limit of audible appreciation. This experiment can be verified with a few feet of gutta-percha covered wire lying on the ground as a condenser and a graphite resistance in circuit with the telephone, after precautions are taken to ensure the necessary degree of insulation in the wire and instrument.

A SIMPLE POCKET POLESTEP.[1]

The need of trimming arc lamps daily first led to the use of a light, but sufficiently long, ladder which the trimmer carried with him on his rounds. Later the upper rounds of this ladder were transferred to the poles, and the general adoption of the so-called polesteps shortened the portable ladder and threatened to stop its use altogether. But to guard against any undesirable manœuvers on the part of the ever present small boy—and of the more dangerous big boy as well—these steps must not go down to the foot of the pole. So the trimmer, in many places, still carries on his rounds a small ladder which reaches up to the lowest of the polesteps.

As a substitute for this ladder a few detachable polesteps may be used, as they are much more easily carried about. Such a device has lately been put on the market and reminds the writer of some home-made polesteps which he saw in use in an eastern town. It was at a place where the circuits spread out several miles in each direction, and many of the lamps were on the hills some three hundred feet above the level of the rest. Such a topography made the carrying of the ladder quite a burden, and the ingenious trimmer soon hit on an easier plan. He drilled three holes into the sides of every pole at about the points where additional polesteps would be placed, slanting the holes slightly downward. Three short wooden pieces, whittled out of a broomstick, formed the steps for which these holes served as sockets. Then with the wooden pegs hung from his tool-belt by little wire hooks, he started out on his rounds better equipped and yet less loaded down than before. These pocket polesteps proved quite a boon to the trimmer and might well be more widely used; while up in a station attic lies a partly decayed trimmer's ladder which may some day be shown to visitors as a relic of early methods.

Mr. J. B. Nelson has resigned his position as manager of the Glens Falls, N. Y., office of the Commercial Union Telegraph Co., and will be succeeded by Mr. Nathan E. Stafford, who has been employed in the office for some time.

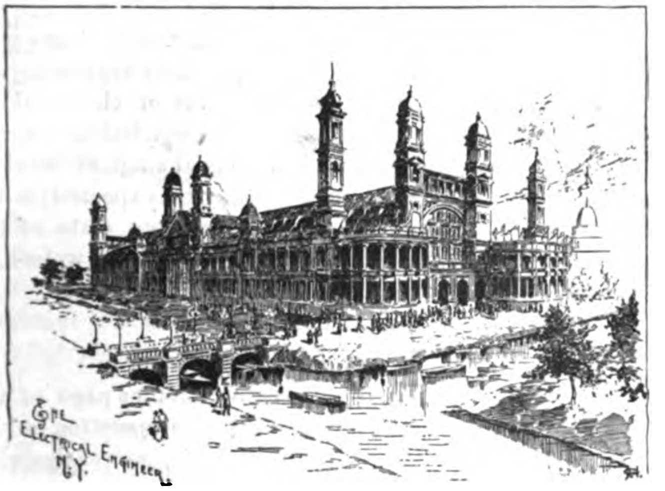
THE ELECTRICAL BUILDING AT THE WORLD'S FAIR.

The chief aim of the architects of the building for the World's Fair electrical exhibit, Messrs. Van Brunt & Howe, of Kanas City, Mo., has been to furnish a structure that will bring out to the best possible advantage the important feature of electric lighting. The towers, the great open portico in the avenue, the flag-staffs, the mural bays and projections, and the windows, were all studied and experimented upon and redevised, in order that no chance might be overlooked.

The dimensions of the building are generous, and yet complaint has been made that it is altogether too small for the purpose. This complaint is just, and it is possible that the building will be enlarged. Its dimensions, as now understood, are 766 feet in length, and 350 feet in width. The area covered is 211,190 sq. feet, or 4.85 acres.

The building is in the style of the Italian Renaissance. At each corner a spire rises to the height of 169 feet, and the rigidity of the rectangular construction is further relieved by other spires and domes, which give a lightness and airiness of design appropriate to its purpose. On the south front is a niche, covered by a half dome, 78 feet in diameter and 103 feet in height, in the centre of which will stand a colossal statue of Franklin.



Electrical Engineer N.Y.

THE PROPOSED ELECTRICAL BUILDING, WORLD'S FAIR, CHICAGO.

The walls exteriorly will be of "staff" a kind of stucco which can be wrought into the exact effect of marble. The porticos and loggia are to be variously enriched with colors. The details of the interior will be made ornate with enriched pediments, panels, friezes, and spandrels. On the frieze in each bay is to be the name of some discoverer or inventor. These names will preserve a chronological order, and will represent chapters in the history of electricity.

GRAPHIC METHOD FOR ANALYZING LOSSES IN ARMATURE CORES, ETC.[1]

BY R. H. HOUSMAN.

It has been found possible, by a simple graphical construction, to separate the different losses in armature cores without any recourse to mathematics at all. The method is as follows: Measure the current required to run the armature as a motor light with different volts on the armature, the magnets being separately excited so as to keep the field constant. On plotting the results as a curve, as in A B, Fig. 1, it will be found that the curve is a perfectly straight line, cutting the axis of current at some distance from the origin.

Now, taking any point B on the curve, and drawing B C parallel to A O, it is evident that the total loss is represented by the product O C × C B.

Next draw A D parallel to O C; this divides the area representing the total loss into two parts, one of which, O D, is proportional to O C, and the other, A D × D B, is proportional to the square of O C, since B D is proportional to A D which = O C. The first of these areas represents the waste of energy per second due to hysteresis and friction combined, while the second gives the loss due to Foucault currents. It must be noticed that it is the product of the co ordinates of any point on A B which represents the waste, and not the area of the figure A O C B. In this respect the diagram resembles the characteristic of a dynamo rather than the diagram of a steam engine.

Hysteresis
G
H
Brush Friction.
E
F
Bearing Friction.
Current in Armature ∝ Torque with given field.
O
Volts in Armature. ∝ Speed with given field.
C

FIG. 1.—GRAPHIC METHOD OF ANALYZING ARMATURE LOSSES.

Friction of bearings and brushes must be determined separately by coupling direct to a similar motor, and observing the increase of current required to drive with the fields unexcited. This will be constant at all speeds.

From this experiment draw O E equal to the current observed as required for friction alone, then E F being drawn parallel to O C, the rectangle O F represents loss by bearing friction. By a similar experiment the loss by brush friction may be determined, and G H drawn, so that E H represents the loss from this cause. The remaining rectangle G D will then show the loss due to hysteresis. It will be readily understood that only the losses represented by G H × H B (Foucault currents + hysteresis) appear as heat in the armature.

A second set of experiments may be made with a different strength of field, and plotted in a curve A' B', which is in general parallel to A B, showing that Foucault currents are constant for given volts. A' B' will be above or below A B, according as the change of field intensity has increased or diminished the sum of the losses due to hysteresis and friction, these two varying inversely, though not in simple inverse ratio.

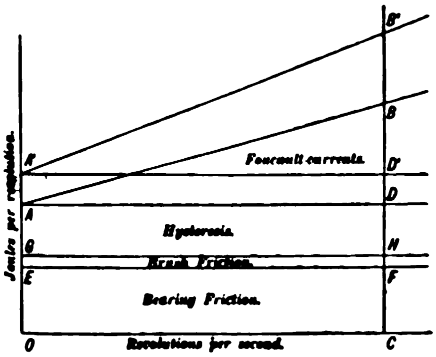

FIG. 2.—GRAPHIC METHOD OF ANALYZING ARMATURE LOSSES.

In Fig. 1, all the quantities have been measured electrically, hence it may be called the electrical curve, to distinguish it from another diagram which may be derived from it, in which the quantities are measured in mechanical units.

In Fig. 2, the same friction line holds good for all intensities, and the frictional and electrical losses are separated by the line G H. It will also be seen that the quantities G A and G A' represent the losses by hysteresis, in Joules per cycle, at the two intensities, for which A B and A' B' are drawn respectively. The loss per cubic centimetre from this cause is always found to be much greater than that generally given.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. XI. NEW YORK, MAY 13, 1891. No. 158.

A patent for an invention forbids no man to carry on the industry and business he has always carried on. It cannot raise the price, for people may manufacture in the old way; the patentee only has the sole right to use the new method he has invented.—James J. Storrow.

THE AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

THE programme published of the Annual meeting of the Institute in this city next week, and the arrangements now announced, go to show that the occasion will be one of great interest and importance. The papers cover a a variety of leading topics, and, with the discussions they elicit, are likely to be additions of permanent value to the literature of the profession. The growth of the Institute from the start in 1884 up to the present time has been steady, and, though never slow, has always been free from "boom" or undue forcing. Its work was long since recognized as on the highest plane, and its membership, now between 500 and 600, embraces the very strength and stamina of electrical engineering in America. Fortunately, too, the Institute will enjoy in its meeting here, the kindly cooperation of the New York Electric Club, the pioneer in its own special work, and a body which has done inestimable service in promoting friendship and social intercourse in a field whose commercial antagonisms have been of the bitterest nature. The working together of these two powerful bodies for a common end—namely, the raising of the standard of electrical thought, action, and influence, in this city and throughout the country—should be attended by notable results; and we venture to hope that the coming week will be one of great pleasure and profit for all who take part in the proceedings at the Institute and the Club.

A STANDARD CHART OF ELECTRICAL DIAGRAMS AND SYMBOLS.

WE have drawn attention on more than one occasion to the necessity which is becoming more and more felt of providing a uniform system of nomenclature in magnetic and electrical work, and the subject has been agitated in various quarters. Several years ago Prof. Jamieson, in a paper read before the Society of Telegraph Engineers and Electricians, pointed out the wide discrepancies which existed, and showed, by references to standard works, the diversity of signs and symbols applied to designate the same things. He suggested at that time a series of standard symbols and signs, but as yet no official action has been taken by any of the recognized electrical bodies in this matter. In the meantime the steady progress of the science and art requires more than ever the establishment of conventional abbreviations and characteristic diagrams, and recognizing this want, Prof. F. B. Crocker has prepared for his students at Columbia College a chart which we reproduce on another page. Prof. Crocker has been careful to select the most characteristic diagrams, and his abbreviations will be found to be those most approved among the electrical fraternity to-day. The diagrams especially will, we are sure, prove of considerable aid, not only to students generally, but to all those who are required to represent pictorially or graphically the various kinds of electrical apparatus and their functions. While electrical nomenclature has probably not yet reached its final stage of development, and changes and additions may be expected in the future, as an accurate record of the present state of the art in this respect, the chart is one which will be welcomed and utilized by many.

STORAGE BATTERY TRACTION.

THE description which we give on another page of the system of storage battery traction now in operation on the Lehigh Avenue Railway in Philadelphia, serves again to draw attention to the requirements of this class of work, and claims consideration on account of the methods employed. It is evident that, given a battery possessed of sufficient length of life, it is immaterial whether it accomplishes its work by delivering a small volume of current at a high E. M. F. or the reverse. In either case the motor can be adapted to the particular conditions of operation. We are led to this reflection by the general impression apparently existing, that a low voltage cell is not adapted for traction work. In the type of cell employed in the experiments described, the working E. M. F., does not exceed .8 volt; but it will be readily seen that the rate at which the batteries can be drawn from in amperes is higher, in the same proportion as the E. M. F. of the lead storage battery is over that of the type of cell used. It will also be noticed the weight of the cell employed to operate a car is very much reduced on account of the employment of copper instead of lead. But perhaps of equal interest, not only from the theoretical, but from the practical standpoint, is the performance of the motor. The curve of ampere readings shows in what manner the energy is restored to the cells when stopping and on down-grades, which, of course, is only made possible by controlling the motor entirely by the switch and without the use of the brake. If the life of the cell of the type employed on this trial shall prove reasonably long, we are free to say that storage battery traction has advanced another step towards being a dominant factor in street railway traction.

ELECTRICITY IN MINING.

THE promising field which the mining industry presents for the application of electricity both to lighting and power purposes has been too often pointed out to require any extended reference at this time, but the importance of a recent development in this field deserves more than passing notice. In many mining operations and in tunneling, the driving of the headings forms a most important part of the cost, and of this the item of labor forms by far the largest fraction. Any apparatus, therefore, which will lessen the time required to bring down a certain quantity of rock, will inure to the direct reduction of expense. We believe that the electric drill in destined to bring about in a marked degree this economy, and the powers of this new instrument as compared with the older types of air and steam drills are well brought out in the paper read by H. Ward Leonard before the Quebec Association of Mining Engineers. The description of the various types of drills adapted for different classes of work is evidence of the fact that there is practically no department of mining which cannot be successfully carried out with the aid of electricity, in most cases with a marked degree of economy and especially so where water powers are available. Mr. Leonard has added considerably to the value of his paper by the addition of a chart and formulae, which if intelligently applied will allow of the most direct calculation of much important data in connection with the installation of both lighting and power plants.

ELECTRICITY AND THE MODERN CITY.

WE took occasion lately to comment on the Census figures relative to electric traction and those which purport to show an undue growth in urban population. While we are fully aware of the existence of many things that render a city more and more attractive, doubt arises in our mind as to whether the last decade has not seen an exaggeration of the cityward tendency from the sore lack of rapid transit facilities. The love of pure air, green grass and waving boughs is as strong to-day as it ever was in the breasts of even the majority of dwellers in a city, but so long as it takes a couple of hours out of each day to go to and from a desirable suburb, so long the majority will be condemned to a narrow city dwelling place. This is "the problem of our great cities" in a nutshell, and the problem can be solved, it seems to us, by bringing the rapid transit facilities, with the aid of electricity, up to the needs of the various crowded communities. An electric express service to Yonkers and New Rochelle, Stamford, Tarrytown, and other towns out in the country, would do more to mitigate and abolish socialistic fume and rant than all the preaching and slumming. The workman who is cheaply carried 20 miles out into the rural parts of this State in 20 minutes to his own home, on May First, is not going to waste his time that day in weary processioning over dusty city stones and under a flaring red flag.

Electric Railway Innovations.

NOTE has been made in these columns now and again of innovations due to the introduction of electric cars, such as special freight service, funeral trains and the like. The flexibility of the method invites to the trial of novelties of this kind, and thus we are not surprised to hear that the handsome Short car in Cleveland has lately been utilized for afternoon teas, so that not only could one sip the social Bohea but make a pleasant, smooth trip through the green avenues. The same car has also, we hear, been used lately by one of the officers of the company in making a tour of inspection of the various suburbs, in search of a new home, stopping at any point and switching from road to road as fancy dictated. Many a weary house hunter would have been glad of such a special car this spring, and we don't see why "afternoon tea" cars and "house hunter" cars cannot be made a profitable feature of the business, just as special theatre cars are.

Lieut. Patten's Alternating Motor.

WE have already had occasion to describe several types of alternating motors designed by Lieut. F. Jarvis Patten, and this week give the two latest forms. In these types Lieut. Patten has ingeniously applied the method of directing the alternating current so that the machine is continuously energized by currents of the same polarity. The pulsating field current employed would naturally require a lamination of the field to avoid losses due to Foucault currents. The motors of Lieut. Patten are interesting examples of the wide range of types available in alternating motor work, being of the class which start as true alternating machines and, when running at their normal speed, are converted into motors of the continuous current type, fed by a rectified alternating currents.

Woman's Work In Electricity.

So little work has been done by women in the field of electricity, that we may be pardoned for calling attention to the fact that we review elsewhere this week two books on electricity, one by Mrs. J. E. H. Gordon, and the other by Emma Marie Caillard. This is a hopeful indication of the manner in which electricity has become part and parcel of daily life, and of the work it still has to do in the home in lessening the burdens of household duties. Women today are doing the bulk of domestic toil in a simply barbaric way, because mechanical power has not been at their command. The modern distribution of electric current is changing all this, and in a few years we shall see a number of electric labor-saving appliances in every house entered by a wire and connected with a central station.

The World's Fair Electrical Exhibit.

WE give in this issue a view of the building that has been designed for the electrical exhibit at the World's Fair, Chicago. Nothing is final as yet, however, and it seems as though considerable provision must still be made for the steam plant, the building shown being intended only for the electrical exhibits proper. There appears also a sad lack of appreciation in some quarter or other of the part that electric motors could be made to play in driving exhibit machinery all over the Fair.

THE ELECTRICAL TRANSMISSION AND CONVERSION OF ENERGY FOR MINING OPERATIONS.[1]

BY H. WARD LEONARD.

THE transmission and conversion of energy is above all others the question of importance in every kind of engineering work, and in mining engineering this is most conspicuously true.

The transmission and conversion of energy by water, steam, cables, compressed air, and so forth, we are all familiar with, and we know to our sorrow the limited distance, the low efficiency or the tremendous first cost which has hampered our engineering work at every turn. With the utilization of electricity for the transmission and conversion of energy we absolutely reverse these conditions and are enabled to operate at practically unlimited distances, with extremely high efficiency and very low first cost.

The great variety of the applications in the mining field, the distance from the mines to the principal cities where electrical developments have been most rapid, and the lack of knowledge as to the exact requirements have, until recently, made even the simplest applications of electricity to mining rather rare. Perhaps the greatest stumbling-block has been the percussion drill. Until recently, when a mine owner asked if we could transmit his power, light his mine and operate his pumps, hoists, tramways and mills, we could confidently reply, "Yes!" But when he asked if we could replace or operate his air drills, we were obliged to say, "Not yet." Since the drill is the most universal of all mining appliances operated by power other than hand power, it was not possible to make rapid progress until this deficiency was corrected.

The Edison General Electric Company has put upon the market in commercial form, during the past thirty days, three types of electric drills which will enable the mining engineer to accomplish all that he has been able to accomplish heretofore by other drills, and not only this, but to accomplish far more than was heretofore possible and under conditions heretofore prohibitory.

First in importance comes the Electric Percussion Drill, the invention of H. N. Marvin, of Syracuse, N. Y.

Following is a brief description of the principal features of the drill:

Fastened upon a suitable tripod or column is a piece of boiler tube seven inches in diameter and about two and a half feet long. In the forward half of this casing are placed two cylindrical coils of wire in the form of solenoids, each about eight and a half inches long, having an outside diameter of about six and three-quarter inches, so as to make a loose fit with the casing, and an inside diameter of about two and one-eighth inches. These two solenoids are placed so as to be against each other, end to end, in the casing. The bit plunger plays freely through the centre of these solenoids and is supported by two bearings placed just beyond the outside ends of the two solenoids respectively. The back portion of the casing contains a spiral spring of the form frequently used for car springs. The plunger is composed of a central portion made of wrought iron about 14 inches long and both the forward and back portion of the plunger, which are made of aluminum bronze, are rigidly fastened to this iron portion. The forward portion is about 13 inches long, and carries the bit socket. The back portion is spirally milled for a length of about nine inches so that the cross section of this portion is hexagonal. At the extreme back end is a steel buffer which strikes against the cushioning spring.

The spirally milled portion of the plunger is similar to that used in other percussion drills, and causes the drill to revolve upon its axis one-sixth of a complete turn with each stroke. The ends of the coils of wire are brought to contact pieces at the top of the adjacent ends of the two solenoids, where there is a socket for receiving the terminals of the cable and thus making electrical connection with the drill. There are three conductors leading from the generator to the drill, one of which is connected to one terminal of each of the solenoids, and the other two conductors are connected to the two remaining terminals of the solenoids respectively.

The generator is of the simplest kind, the coils on the armature having their terminals connected to two insulated collars on the shaft.

One collar is a continuous metallic ring, and upon this one rests a brush which is connected with the conductor, which is common to both solenoids. The other collar is metallic for half of the circle, and the remaining half is insulated from the armature wires. Upon this half ring rest two brushes diametrically opposite each other, and each brush is connected to one of the two remaining conductors leading to the solenoids in the drill.

If we now revolve the armature of our generator in a separately excited magnetic field an electric current will flow, let us say, from the armature to the half ring, then through one of the two brushes which happens at the instant to be in contact with the half ring along the corresponding conductor to one terminal of one solenoid, let us suppose the rear one. Then through the rear solenoid itself and back along the mutual wire to the continuous ring, and then to the armature again. This current in passing through the rear solenoid makes a powerful magnet of it, and this tends to pull the plunger back into a position such that the centre of its iron portion shall be in the centre of the rear solenoid.

When the armature moves forward a half revolution the polarity of its wires is reversed and the other brush with its conductor is now in contact with the half circle. Consequently, the current in the mutual wire will be in the reverse direction from that of the former wave; the rear solenoid and its conductor, formerly active, are now out of circuit, and the circuit is made through the other conductor and its corresponding solenoid, that is, the forward solenoid. The magnetic action of this solenoid now tends to make the plunger move forward so that the centre of the iron portion shall be in the centre of the forward solenoid.

Thus we get a reciprocating action of the plunger and every revolution of the armature of the generator will cause a complete stroke of the drill. By varying the speed of revolution of the generator we can make the drill strike any number of blows, per minute, we choose. In usual practice 600 blows per minute is found to give excellent results. The spiral spring, it will be observed, stores up the energy of the back stroke and returns it to the forward stroke, assisting the magnetic impulse and greatly increasing the strength of the blow.

Besides possessing the requirements of a first-class power drill, as stated by Andre many years ago, the Marvin drill has many other advantages not possessed by the steam or air drill; thus, it takes up very little space, and the length of the stroke is variable at will.

It will operate in the open air without striking anything, and hence can be made to strike an extremely light blow at its full rate, which is very important in starting holes, and so forth. It can be rapidly moved from one position to another at a great distance, since the energy is transmitted through flexible cables. No loss is suffered due to elbows, bends, valves, and so forth, in the conductors, and the efficiency of the drill itself is greater than that of any other type.

The importance of the above characteristics will be apparent to any one who is familiar with the operation of the steam and air drills. It is interesting to note that in driving the Hoosac Tunnel the average life of the power drills, before sending them to the shop, was 50 hours. Even to-day, after a development of 25 years, we find that it is common practice to have in the shop one-half the total number of drills employed.

To increase the rate of drilling we must either increase the strength of each blow or else we must increase the number of blows per minute. But the strains and shocks caused by the valve and the air or steam soon become troublesome as we increase the rate of striking. With the electric drill the speed of rotation of a perfectly balanced cylindrical armature of small diameter has no such limitations and there is apparently no limit to the rate of striking, except the magnetizing and demagnetizing of iron which is already done in daily commercial practice at the rate of 10,000 times per minute with the highest efficiency. With 800 blows per minute we have already drilled at the rate of four inches per minute a hole 1½ inches in diameter in the hardest Quincy granite, and that with an expenditure of energy not exceeding 3 h. p. I firmly believe that in a comparatively short time we will be furnishing percussion drills whose rate of striking will be several times as much as that we now employ, and that, with no more and no heavier drills than are now used, the rate of driving a heading will be increased many times.

A bulletin from the Census Department, under date of March, of this year, shows that in granite quarrying the cost of labor is 84 per cent. of the total cost of production, and in Massachusetts, where the out-put is much greater than in any other state, and where the longest experience and most approved methods are met with, the labor is 82½ per cent. of the total cost. It will be evident that any labor saving device in such a field will be extremely valuable.

Another drill of great value to the mining engineer is the diamond drill. The Edison General Electric Company have, during the past thirty days, put upon the market an electric diamond drill which they have been developing for the past two years. The drill is the invention of I. E. Storey, of Denver, Col. It presents a great many advantages over the diamond drills heretofore used, as will be evident from the following description of it.

The drill weighs complete 239 pounds. The average power consumed is about 1¾ h. p., and with this expenditure of power the drill will bore a hole of 1¼ inches diameter in hard rock at the rate of two inches per minute, taking out a core of ¾ of an inch. The drill rod is rotated at the rate of 400 revolutions per minute without any load and when drilling at full load the speed is practically the same.

The drill rod is geared by a single set of gears to an electric motor which revolves at 1,600 revolutions under conditions of full load. The motor has four poles and the keeper joining the poles is in the shape of a surrounding cylindrical shell, which thoroughly protects all the parts of the motor and other parts of the machine. Upon the drill rod is placed a rotary pump which supplies the drill with the necessary water.

---

[1] Abstract of a paper read before the Association of Mining Engineers of the Province of Quebec, April 29, 1891.

RESUME OF FORMULAS FOR DEVICES IN MULTIPLE ARC.

Compiled By H. Ward Leonard.

				Size.	Weight.	Cost.
Conductors as determined by losses therein.	Incandescent Lamps.	Two Wire System.	General Cases.	$M = \frac{\text{T. c. p.} \times D \times 16.000}{e \times V \times \text{C. h. p.}}$	$T = \frac{D^2 \times \text{T. c. p.}}{V \times e \times \text{C. h. p.} \times 1{,}000.}$	$\$ = \frac{D^2 \times \text{T. c. p.} \times L}{V \times e \times \text{C. h. p.} \times 1{,}000.}$
				$M = \frac{\text{T. c p.} \times D \times W \times 21.5}{e \times V}$	$T = \frac{D^2 \times W \times \text{T. c. p.}}{V \times e \times 746{,}000}$	$\$ = \frac{D^2 \times W \times \text{T. c. p.} \times L}{V \times e \times 746{,}000.}$
			For 100 volt lamps 4.66 watts per c. p.	$M = \frac{\text{T. c. p.} \times D}{V}$	$T = \frac{D^2 \times \text{T. c. p.}}{V \times 16{,}000{,}000.}$	$\$ = \frac{D^2 \times \text{T. c. p.} \times L}{V \times 16{,}000{,}000.}$
			For 110 volt 3.1 watt lamps.	$M = \frac{\text{T. c. p.} \times D \times 2}{3 \times V}$	$T = \frac{D^2 \times \text{T. c. p.}}{V \times 24{,}000{,}000.}$	$\$ = \frac{D^2 \times \text{T. c. p.} \times L}{V \times 24{,}000{,}000.}$
		Three Wire System.	General Cases.	¼ of corresponding 2 wire case.	⅓ of corresponding 2 wire case.	⅓ of corresponding 2 wire case.
			For 100 volt 4.66 watt lamps.			
			For 110 volt 3.1 watt lamps.			
	For any case.			$M = \frac{C \times D \times 21.5}{V}$	$T = \frac{C \times D^2}{V \times 746.0}$	$\$ = \frac{C \times D^2 \times L}{V \times 746{,}000.}$
	For power at motor pulley.			$M = \frac{D \times \text{h. p.} \times 1{,}600}{V \times e \times P}$	$T = \frac{D^2 \times \text{h. p.}}{V \times e \times 10 \times P}$	$\$ = \frac{D^2 \times \text{h. p.} \times L}{V \times e \times 1{,}000 \times P}$
	For minimum total initial cost of plant.					$\frac{G \times E \times V}{(E - V)^2} = \frac{G \times p \times 100}{(100 - p)^2} =$ Dollars per h. p. del. by conductor.
Generators for minimum total initial cost of plant.						$\frac{100\ G}{100 - p} =$ Dollars per h. p. delivered by conductor.

Conductors as determined by safe heating.	Bare Copper Wire.	15° C.	$M = C^{\frac{4}{3}} \times 200.$
		35° C.	$M = C^{\frac{4}{3}} \times 170.$
		45° C.	$M = C^{\frac{4}{3}} \times 100.$
	Average Insulated Copper Wire.	15° C.	$M = C^{\frac{4}{3}} \times 150.$
		35° C.	$M = C^{\frac{4}{3}} \times 100.$
	Bare Iron Wire.	45° C.	$M = C^{\frac{4}{3}} \times 328.$
	Bare German Silver Wire.	45° C.	$M = C^{\frac{4}{3}} \times 608.$

E = E. M. F. of generator in volts.
e = " " device "
C = current in amperes.
c. p. = candle power of lamps at normal E. M. F.
T. c. p. = total candle power of lamps.
C. h. p. = candle power per electrical horse-power at normal E. M. F.
M = area of cross-section of wire in circular mils.
D = mean distance current is transmitted one way.
V = loss of E. M. F. in conductor (in volts).
$\$$ = cost in dollars.
L = cost of copper per pound in cents.
W = watts per candle-power.
T = weight of wire in pounds.
P = efficiency of device.
p = percentage loss in conductors.
G = cost of generator per h. p. delivered by conductor.

With the electric drill the motion is free from any jar due to the reciprocating engines heretofore employed, as there are no reciprocating parts, and the speed can be made absolutely constant under any condition of load up to the full load. The weight of the electric diamond drill is, for the same power, much less than that of the steam diamond drill and the space occupied is in a direct line with the hole and is extremely small in amount.

The drill can be operated from any existing electric light circuit and the current for it can be supplied at two miles' distance from the source of power by wires of size No. 10 B. W. G. having a diameter of about ⅛ of an inch. The drill can be carried wherever a man can carry 85 pounds, which is the weight of the heaviest single piece, and hence can be set up and operated in the most inaccessible places. It will be evident that for prospecting work, when a certain territory is to be explored, this drill is particularly adapted, as for operating at a distance of one mile in any direction the diameter of the wire neccessary is but 1/10 of an inch and the total weight of the wire only 340 pounds.

The Edison General Electric Company have a third kind of drill which is a rotary high speed drill, having a solid steel bit, and this drill is used for drilling coal and similar comparatively soft materials, and also for drilling metals where it will have an extensive use in the construction of steel ships and bridges and similar works where the drill has to be taken to the work rather, than the reverse.

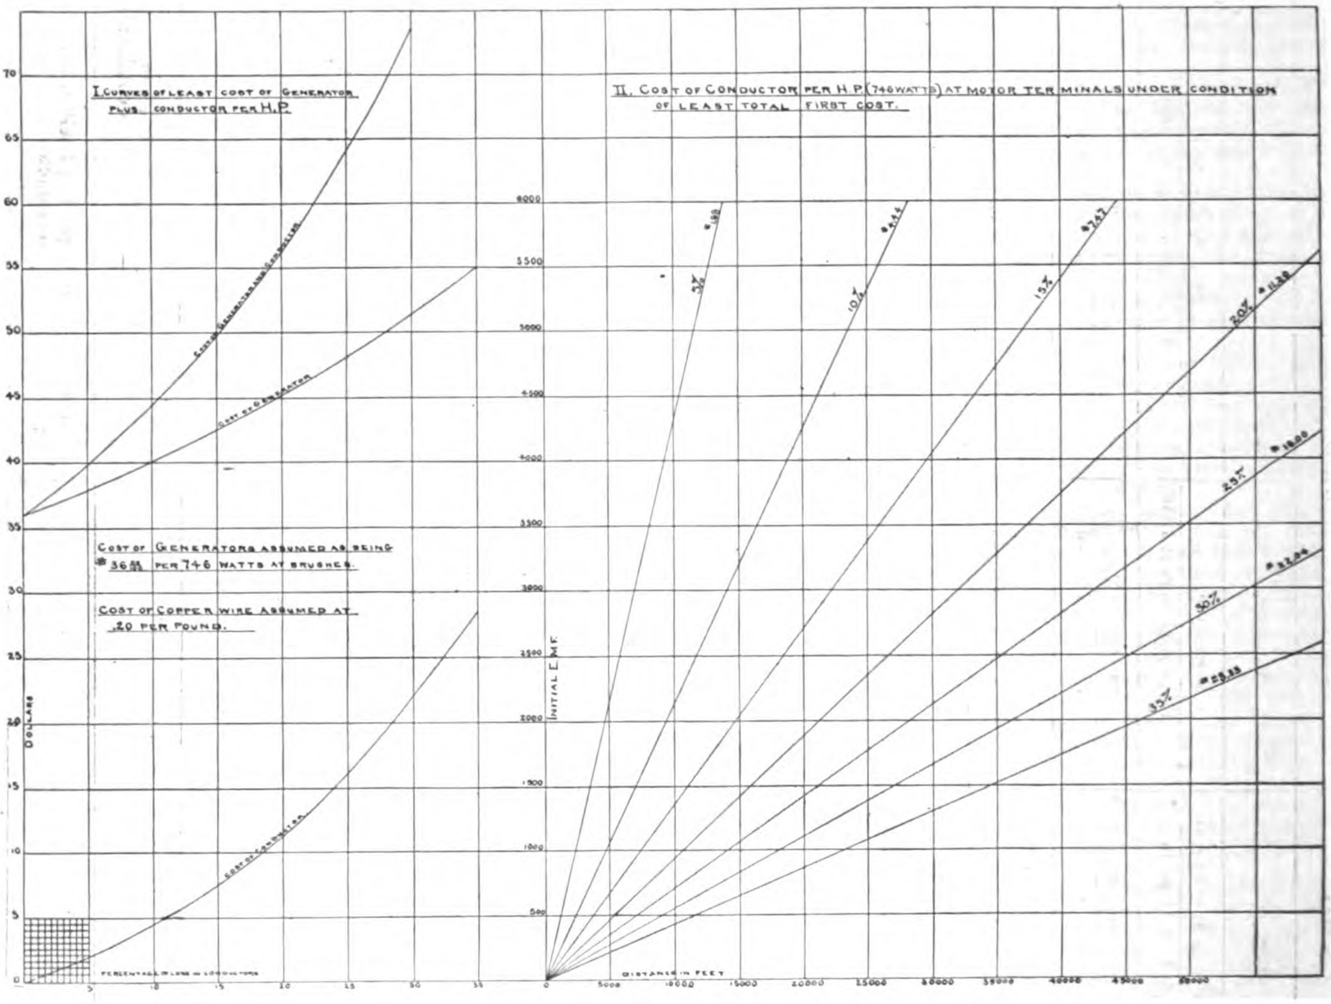

Fig. 2.—Curves Showing Least Total First Cost of Generators and Conductors.

The electric mine locomotive, and the hoists, pumps, ventilating fans, crushes, stamps, and so forth, operated by electricity are instances of the application of electricity to mining which have already proved themselves entirely successful. The under-cutting of coal by electricity is an important field in which the Edison company has made great strides, the machines being of two entirely distinct types, which becomes necessary in order to properly comply with the conditions met with in practice in different mines.

The electric refining of metals, especially of copper, is an extremely interesting subject to the mining engineer. The Edison Company have established the majority of the plants of this nature in the United States; and I need only say that the results are highly economical and most satisfactory in every way.

The electrical transmission and conversion of energy at great distances is destined to come up in nearly every mining problem in the future. Mines are usually in a mountainous country, and it is seldom that a water-power cannot be found within a few miles of a mine. The mining engineer in the immediate future will develop this water-power, convert its energy into electric energy, in which shape he will transmit it to the distant mine, when it will be again converted into the various forms of energy which he may have occasion to require.

Among the applications will be the following:

1. The lighting of the mines and the buildings and grounds by arc and incandescent lamps; 2. The operation of any machinery in the mill, such as crushers, stamps, and so forth; 3. The operation of the drills; 4. Hoists; 5. Pumps; 6. Ventilating fans; 7. The operation of an electric tramway in the mine; 8. The heating of the buildings when fuel is scarce; 9. The refining of copper and recovery of gold and silver in certain cases; 10. The concentration of magnetic ores in certain cases, such as iron, nickel, etc.

In order to give you a commercial idea of a plant, such as is likely to be used in mining operation in the immediate future, I will suppose a case and give you an estimate of the first cost and operating expenses of such a plant. Let us suppose that we have a mine where we have to operate the following devices:

360 incandescent lamps at 16 c. p. each; 10 arc lights; 1 hoist requiring 30 h. p.; 1 pump requiring 20 h. p.; 6 percussion drills for drilling 1½ inch holes at the rate of 3 inches per minute; 3 rotary diamond drills 1¼ hole, ¾ core, rate 2 inches per minute; 1 mine locomotive 10 h. p.; milling machinery requiring 30 h. p.; heating requiring 10 h. p.

The total power required for the above will be 180 h. p., delivered by the main motors. Suppose that at a distance of three miles there is a good water power which can be developed and equipped with water wheels to produce 300 h. p. by an expenditure of $15,000. In considering transmission of the power by electricity we must first determine what loss we shall sustain in transmission, and then we must determine what electrical pressure we will operate with.

In designing such a plant there are certain fixed laws governing the conditions of highest economy and minimum first cost; and some years ago I investigated these questions and produced formulæ expressing these laws. These formulæ are given in tabular form in the accompanying résumé, Fig. 1. I have also expressed the laws governing the conditions of minimum initial cost graphically in the diagram, Fig. 2.

It may be interesting to note here in passing, a fact which you will observe by examining the formulæ given, namely: If we pay proper attention to the laws governing the highest efficiency and the least first cost, the cost of the conductors for the plant will depend solely upon the initial E. M. F. and the distance. Thus, under practical conditions to-day, if we are to operate with 2,000 volts E. M. F. at a distance of 5 miles, the minimum first cost would be realized when we operate with a loss of 20 per cent. in conductors. The cost of copper (at 20 c. per lb.) for each horse-power delivered at the motor brushes under these conditions would be $7.47. This simple but invariable law which is embodied in the formulæ given herewith, you will find of great assistance to you in considering questions of electrical transmission.

You will also notice that the formulæ show that, for any given percentage of loss, the electrical pressure to be employed will vary directly with the distance. Thus, for 20 per cent. loss the cost of copper being $11.20 per horse-power delivered at motor brushes, the E. M. F. necessary for transmission of 16,000 feet will be 1,500 volts; at 32,000 feet we should use 3,000 volts, and at 8,000 feet, 750 volts. In order to secure the 160 h. p. necessary at our various devices in and about the mine, we must deliver 200 h. p. to our main motor in the form of electric energy in the conductor at the brushes of the motor. With 25 per cent. loss in conductors this will mean 266 h. p. at the generator brushes, or 300 h. p. delivered by the water wheels.

For the sake of reliability and economy we will use two generators instead of one, each being of 133 h. p. At the mine there will be two main motors of 90 h. p. each, wound for 900 volts and 83 amperes, producing a total of 180 h. p. which will drive the drill generator at 17 h. p., and a generator of 250 volts and 300 amperes for operating the incandescent lamps, the arc lamps, the locomotive, the hoist, the pump, the diamond drills and the heating. The main motors will also supply the milling machinery with the necessary 30 h. p.

By formulæ on Fig. 1, we find that to transmit 180 h. p. three miles, with 25 per cent. loss and an initial pressure of 1,200 volts, there will be required a wire having a circular millage of 190,000 circular mils; this wire has a diameter of 436 thousandths of an inch, or a little less than half an inch. We find that by other formulæ on Fig. 1 that the copper will weigh 20,000 lbs. and will cost $4,000, which results check each other and prove the accuracy of the calculation.

We are now able to make an estimate for the total plant, as follows:

Estimate of cost of plant for transmitting 180 h. p. a distance of three miles with a loss of 25 per cent. in conductors, the plant to comprise the apparatus as specified:

Developing original water-power and installing water wheels of 390 h p.	$15,000
2 generators 100 KW. each (1,200 v.—83 amp. each) at $36 per KW.	7.200
2 motors 75 KW. each (900 v.—83 amp), at $36 per KW.	5,400
Copper, 32,000 feet, No. 000, B. W. G.	4,000
1 6 drill generator.	2,000
1 generator of 250 v. 300 amp. 75 KW. at $36.	2,700
6 electric percussion drills.	3,300
2 electric diamond drills.	1,100
360 incandescent lamps and appliances.	360
10 arc Lamps.	220
1 30 KW. hoist.	2,255
1 20 KW. pump.	1.595
1 10 KW. locomotive.	1,815
Heaters, 10 KW.	600
Conductors for all secondary transmissions.	1,000
Labor of installation.	3,000
Poles.	455
Freight, cartage, and sundry expenses.	1.000
Total.	$53.000

The operating expenses of such a plant will be those mainly due to the wages of the men for each shift, one at the water-power and one at the mine. A fair allowance for depreciation and repairs will be 5 per cent. per annum of the first cost.

The operating expenses will therefore be about as follows:

1 First operator	$ 900	per year.
1 Second operator.	600	"
Depreciation and repairs 5 per cent. on $53,000.	2,650	
Sundry incidental expenses.	250	
	$4.400	

The production of the same power by steam, when coal is $2 per ton, and labor such that an engineer's wages are $2 per day, would be not less than double this amount; and in many instances where water and fuel suitable for the generation of steam are difficult to obtain, such a plant would represent a saving of its entire first cost every year.

Society and Club Notes.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

Further arrangements have been made for the annual meeting in this city, by the local committee, which consists of Messrs. Foster, Caldwell, Thorburn Reid, and Binney. The regular meetings will be held at the house of the Institute, 12 West Thirty-first, where a collation will be served between the morning and afternoon sessions on May 20 and 21. The Wednesday evening session will be held in Prof. Dwight's room at Columbia College, 49th street and Madison avenue, at 8.30 P. M. A lecture will be delivered by Mr. Nikola Tesla, on "Experiments with alternating currents of high frequency." This will be illustrated by practical experiments with special apparatus devised for the occasion. Ladies are invited to attend this lecture.

The Electric Club has courteously extended to the Institute the full privileges of the club house, 17 East Twenty-second street, during the period of the meetings. Thursday, May 21, at 8 P. M., a reception will be tendered to the Institute at the club house. Special interest will be given to this reception by reason of the fact that the entertainment committee of the club has arranged for a loan exhibition of early electrical books, apparatus, models and paintings.

An official invitation has been extended to the Institute to be represented at the Electrical Congress of the Frankfort Exhibition. It is expected that delegates will be appointed and instructed accordingly.

There is every indication that the meeting will be one of the largest and most successful enjoyed by the Institute.

FRANKLIN EXPERIMENTAL CLUB.

The Franklin Experimental Club, of Newark, N. J., held its thirty-first regular meeting at the Club Laboratory, Tuesday evening, May 5th. The president, Mr. Wm. J. Hammer, read a highly instructive paper entitled "The Arc Light." As illustrating the rapid development of this industry, the speaker instanced the fact that while there was exhibited at the Centennial Exposition in Philadelphia, in 1876, but a single arc system, the Wallace, now arc lamps are burning everywhere and are numbered by the thousand and the hundreds of thousands. Mr. Hammer summed up the problems confronting the arc light men and spoke of the field for invention in alternate current lights. The paper was illustrated by diagrams prepared and mounted for the occasion.

Mr. F. M. Crane spoke on electric rail roads. He compared the three systems which are striving for supremacy in this field: the trolley, the storage, and the conduit.

At the next meeting, May 19th, Prof. Geo. C. Sonn will deliver a paper on the phenomena of earthquakes, and will illustrate with lantern slides. Mr. Earl Atkinson will speak on motors.

At the first meeting in June, it is expected that Mr. Nikola Tesla will address the club.

College Notes.

CORNELL UNIVERSITY.

Mr. Frank C. Perkins, electrical engineer, 209 Central avenue, Dunkirk, N. Y., has just issued a charming and most interesting book entitled "Cornell University: Her General and Technical Courses." It is in oblong form, with heavy ornamental board covers, and is profusely illustrated with views of the famous University, and portraits of the various professors and instructors. Mr. Perkins has done his work with intelligence and taste, and there is not anyone who, if interested in Cornell, will not be delighted to possess a copy of this brochure. We are glad to note excellent portraits of Profs. Nichols, Moler, and Ryan, of the electrical department.

FARMING vs. ELECTRICITY.

The following pathetic little bit of correspondence between two of the "old timers" in the electric railway business recently fell into our hands: "Looking over the figures bid on a recent large contract—don't you think that veterans, like you and me, had better quit and go farming?" There is a depth of feeling in this that many can appreciate, but it is devoutly to be hoped that these two mourners will still stick to a field in which they have both greatly distinguished themselves—many a time. Should they become farmers, we are sorry for the Alliance. It will be the liveliest third party this country has ever seen.

THE STEWART CONDUIT FOR ELECTRIC RAILWAYS.

BY R. A. STEWART, PITTSBURGH, PA.

Considering the attention that is being given to underground conduits for electric railways, and the persistently continued objections to the unsightly, if not dangerous, poles and overhead wires, it is evident that underground conduits are destined to become a prominent feature of electric railway work. But objections have been found with underground conduits as heretofore constructed, principally to the open or vertical slot, in which horses' shoes and narrow tired vehicles are alike liable to be caught, and into which the water and refuse of the street flow freely. The main, practical objection, however, has been to the expensive construction necessary in a conduit which forms no part of the tracks but which must be built of itself. To overcome these objections I have had patented a conduit which is a part of the tracks and which has a protected side slot. In the accompanying cuts Figs. 1 and 2, one form of construction is shown.

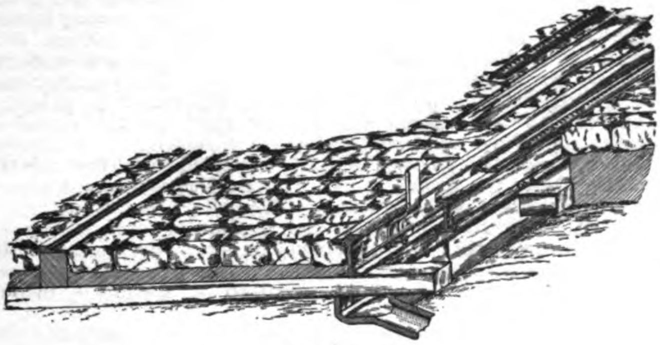

FIG. 1.

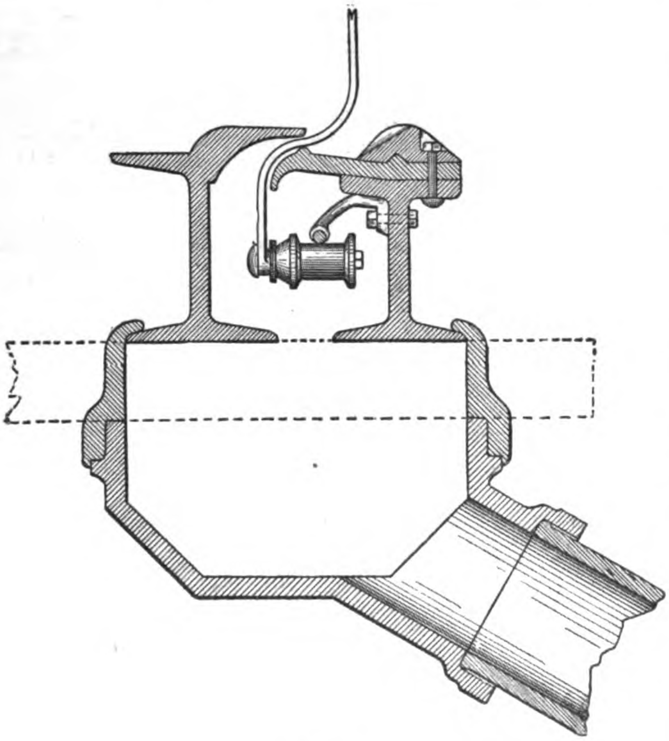

FIG. 2.

The rail on which the car wheel runs forms one side of the conduit. The other side is formed by a girder rail on which is a detachable tread and ribbed faced rail. This supplementary tread rail is overlapped by the main tread rail, forming a slot between them extending sidewise into the conduit. Horses cannot catch their shoes in this side slot and very little if any mud or water will pass through it into the conduit.

The supplementary tread rail slopes away from the slot to the ribbed-faced rail, forming a trough which carries the mud or water away from the slot and out through deep indentations in the ribbed faced rail to the street.

This trough will also take the wagon wheels and thus relieve the main rail of any undue pressure, the ribbed faced rail allowing the wheel to catch and turn off quickly and without sliding.

Any mud or water that could get into the conduit will be carried off by the drain at the bottom, which is made of tiling and is connected at intervals with the sewer.

A depending lip on the supplementary tread rail extends over and protects the electric conductor from outside interference and also prevents any drippings through the slot from lodging on the conductor, whether the conductor be hung for underrunning or overrunning contact, either of which is allowable.

A particular advantage of this conduit over others, is the ease with which access can be had to it for inspection or repairs. By simply detaching the supplementary and ribbed-faced rails, free access is obtained into the conduit without interfering whatever with the running of the cars or with the street traffic.

The cost of construction which has been a drawback to most underground conduits is a decided advantage to this one. The car track forming one side of the conduit, it only requires the additional expense of the one other side, and it is evident that this will be far less than a conduit necessarily built of itself and forming no part of the tracks on which the cars must run.

Reports of Companies.

WESTINGHOUSE ELECTRIC AND MFG. CO.

The annual meeting of the stockholders of the Westinghouse Electric and Manufacturing Company, in accordance with the by-laws of the organization, was called for Monday, May 4th, 1891. A good deal of interest was of course felt by the local stockholders of the company in this meeting and it was looked forward to with some anxiety. The expectation was that Mr. Westinghouse would give in detail the result of his negotiations made during the last few months with the view of putting his company upon a good basis financially. At the meeting, fifty stockholders were present. Mr. Westinghouse presided and after the formal opening of the meeting, the following statement was read by him:

"The annual meeting of the stockholders of this company was called for this day in compliance with the by-laws, which fix this day for the day of the annual meeting. The directors at a meeting held this morning, passed the following resolution: 'It is moved that in view of the fact that in the opinion of this board it is not advisable to announce at this time the details of the plan for placing the preferred stock of this company, liquidating its floating debt and securing working capital which has been substantially completed, the stockholders be requested to adjourn the annual meeting called for to-day to Monday, May 18th, 1891, at 10 o'clock in the forenoon, in room 64, Westinghouse Building, Pittsburg, Pa.' In the negotiations, which have been so nearly concluded, the interests of the present stockholders have received special consideration, with a view of giving a permanent value to their stock. The business of the company has been continued without interruption, and although with a lesser volume than for the same period last year, the net results have been better. The orders in hand and those being received are equal to the capacity of the works, and it is expected that the arrangements which have been made will soon put the works of the company in full operation. A large reduction in expenses has been effected, by reason of which, and a more conservative business policy, the affairs of the company have been steadily improving since the first of January."

Upon the request of Mr. Westinghouse, after the reading of this statement, Mr. Frank Whitesell, a Pittsburgh lawyer, moved that the meeting adjourn until Monday, May 18th, at 10 o'clock, A. M. This resolution was passed unanimously.

To the above it may be added that a syndicate, consisting of August Belmont & Co. of New York; Lee, Higginson & Co. of Boston, and Brayton Ives, President of the Western National Bank, has been formed to undertake the reorganization of the Westinghouse Electric and Manufacturing Company and its associated interests. This syndicate, together with certain creditors of the company and others, has agreed to take $3,000,000 of 7 per cent. preferred stock upon the assent of the stockholders to the plan of reorganization.

Messrs. August Belmont, Marcellus Hartley, Henry B. Hyde, and Brayton Ives, of New York, and Charles Francis Adams and Charles Fairchild (of Lee, Higginson & Co.,) of Boston have consented to become directors.

According to the plan the $100,00,000 capital is not to be increased. The holders of the $7,000,000 common stock outstanding are to surrender into the treasury 40 per cent. of their holdings, which, with the $3,000,000 issued but not sold will make about

$6,000,000 of treasury stock. Of this $4,000,000 is to be converted into 7 per cent. stock, of which the $3,000,000 specified above is to be issued to care for the floating debt and provide working capital, and $500,000 is to be held in the treasury to provide further capital when neeeed. A part of the remaining treasury stock is to be used to purchase further stock in the United States Electric Lighting Company and the Consolidated Electric Light Company, in both of which companies the Westinghouse Company is already interested.

It is understood that this plan not only meets with the approval of the directors and the bankers, but has also been examined and approved by prominent stockholders and creditors.

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED MAY 5, 1891.

Accumulators:—

Secondary Battery, G. A. Washburn, 451,540. Filed July 23, 1890.
Includes an insulating casing for the cells having a cup-lining of conducting material, an inner wall of conducting material apart from said lining, and active material between said wall and lining, and a battery element centrally placed within the case.

Secondary Battery, G. A. Washburn, 451,541. Filed Oct. 24, 1890.
Includes a porous cup containing hollow compressible conductors, an electrode outside of the cup formed of opposed conducting-plates, and active material between the outside plates and in the porous cup.

Secondary Battery, T. H. Aldrich, 451,445. Filed Dec. 27, 1890.
The electrode consists of a body of active material formed with an aperture adapted to receive a conducting plate, and a conducting-plate taking loosely into the body of active material.

Alarms and Signals:—

Multiple Signal Transmitter, B J. Noyes, 451,512. Filed Sept. 22, 1890.
Combines a train and a let-off with a removable signal-wheel and means controlled by the signal-wheel for moving the let-off.

Temperature Alarm, L. Zagelmeyer, 451,543. Filed Dec. 8, 1890.
A thermostatic device including a thermometer.

Alarm Signal, M. A. O'Donnell, 451,639. Filed Mar. 17, 1890.
Permits a policeman to use his club upon the signal box rather than upon his prisoner. Device in the handle of the club for operating signal box.

Signal Box, M. G. Davis, 451,689. Filed June 18, 189.
Improvement upon the signal box patented to M. Martin, Dec. 20, 1887, No. 375,083.

Fire Alarm Telegraph Apparatus, J. W. Stover, 451,902. Filed Jan. 23, 1888.
A non-interference signal box.

Conductors, Conduits and Insulators:—

Insulated Electric Conductor, J. B. Williams, 451,586. Filed July 12, 1890.
A device to keep the conductors concentric with the dielectric employed as an insulator when the latter is of a nature to be readily softened by heat. Consists in a support for the conductor composed of fibrous material saturated with an insulating material not so readily softened by heat as the dielectric.

Insulated Electric Conductor, J. B. Williams, 451,587 Filed Nov. 13, 1890.
For the same purpose as the next above. Differs in detail.

Electric Conductor, J. D. F. Andrews, 451,605. Filed Oct. 31, 1890.
Relates to cables combining a direct and return circuit, and is designed to secure a water tight protection and to afford facilities for joints and connections at desired points without impairing the insulation.

Underground Electric Wire Conduit, H. B. Cobb, 451,614. Filed April 29, 1890.
Employs supports spacing the conductors and secured to the conductors independently of the walls of the conduit, the supports being provided at intervals along the conductor and being movably supported in the conduit. Includes also devices for house connections from the conduit at desired points.

Dynamos and Motors:—

Dynamo Electric Machine, L. C. Rice, 451,574. Filed May 14, 1890.
Relates to alternate current machines. Details of design and construction of field magnets and armature intended to increase efficiency and to facilitate repairs.

Electric Motor, W. E. Hyer, 451,559. Filed Nov. 26, 1890.
The field-magnet has a single coil surrounding the armature and located in a plane oblique to the armature shaft; the magnetic circuit is composed of two hollow castings bolted together on a plane including the armature shaft.

Dynamo Electric Machine, L. N. P. Poland, 451,700. Filed May 7, 1888.
A construction designed to save space and to secure better ventilation. Includes also a regulating device.

Method of Operating Reciprocating Electric Engines, C. J. Van Depoele, 451,786. Filed Jan. 3, 1891.
Consists broadly in employing one set of coils adapted to be energized by an intermittent direct current and another set of coils energized by alternating currents having a defined rise and fall.

Electric Motor, E. M. G. Hewett, 451,870. Filed Nov. 14, 1890.
A motor of the type in which a series of electro-magnets surround an armature composed of bars of soft iron.

Electric Motor, F. M. LaBolteaux, 451,872. Filed June 4, 1890.
Details of construction for small motors and for mounting them to drive fans or other mechanism.

Electric Motor or Dynamo Electric Machine, S. S. Wheeler, 451,884. Filed April 23, 1890.
In a ring armature the core is formed with trapezoidal slots or openings in its periphery; the coils or windings laid in the slots and passing through the inside of the ring form trapezoidal shaped coils or sections which fill the slots in the periphery and in the inside of the ring fit against each other and fill the interior, the coils being thus made symmetrical with respect to the outside and inside of the ring.

Method of Constructing Field-Magnets of Electric Motors, S. S. Wheeler, 451,885. Filed Sept. 13, 1890.
Consists in boring the yoke or base and trimming the ends of the field forgings with reference to the centre of their concave parts.

Electric Motor or Dynamo Electric Machine, W. F. Collins, 451,894. Filed April 17, 1888.
Similar to the next above, but does not show ring windings. Claim follows:
An armature core for an electric motor or dynamo-electric machine formed with trapezoidal slots in its periphery of greater width at the bottom than at the top, the windings or conductors being contained in the slots
Designed to secure a minimum amount of magnetic resistance between the armature and the field-magnet cores and to diminish the evil effects of centrifugal force upon the armature windings.

Lamps and Appurtenances:—

Socket for Incandescent Lamps, S. Deacon and M. J. Wightman, 451,656. Filed March 15, 1890.
Relates to details of the circuit-breaking switch in the lamp circuit.

Current Regulator for Electric Lamps, C. H. Balsley, Jr., and E. M. Porter, 451,798. Filed Jan. 17, 1891.
A current regulator adapted to be inserted in the socket of an incandescent lamp. Consists essentially of a rheostat composed of graphite rods and means for inserting them in circuit.

Measurement:—

Electric Meter, E. W. Rice, Jr., 451,590. Filed March 8, 1889.
Designed for use with currents of any character, continuous, alternating, or intermittent. Employs the heating effect of a current upon a pair of expansible bars, so mounted that neither shall be heated by radiation or conduction from the other, switching devices for heating the bars in turn, and means for registering the movement of the bars under expansion.

Miscellaneous:—

Combined Switch and Lightning Arrester, E. W. Rice, Jr., 451,591. Filed March 5, 1890.
Particularly for use on electric cars. Combines with a manual circuit-breaking switch a blow-out magnet having poles adjacent to the contact points of the switch, and a supplementary lightning arresting contact adjacent to the poles of the magnet and connected to ground.

Magnetic Attachment for Windows, T. N. Sterry, 451,606. Filed July 2, 1890.
A device for holding window sashes firmly in position and to prevent rattling.

Electric Stop Motion, C. A. Dayton, 451,649. Filed April 21, 1890.
Applicable to stationary steam engines, and intended for use in connection with the speed-governor and to enable an engine to be stopped from a distant point.

Railways and Appliances:—

Electric Brake, J. M. Payne, 451,514. Filed March 31, 1890.
An electro-mechanical car brake.

Electric Railway Truck, W. H. Knight, 451,491. Filed Feb. 15, 1890.
Two electric motors mounted upon the two axles of a truck have inward extensions flexibly united at their inner ends to permit freedom of radial adjustment of the axles.

Electric Railway System, C. K. Harding, 451,637. Filed Oct. 27, 1890.
Combines an insulated main conductor, a series of stationary main conductor contacts, protected in insulated cups, with electric cars having current collectors carried thereunder, and a movable circuit-completing device normally insulated from the main supply conductor but adapted, when actuated, to make contact with the main conductor.

Mechanism for Carrying Trolley-Wheels Underground, J. Holland, 451,691. Filed Dec. 22, 1890.
A device for avoiding a continuously-open slot in conduit electric railways. The conduit is closed by a series of doors, hinged at opposite sides of the conduit and meeting in the centre; the trolley carrier is adapted to open the doors successively sufficiently to permit its passage through the conduit.

Electric Railway, R. M. Hunter, 451,692. Filed Apr. 28, 1888.
Relates to a system of switches for a main line of an electric railway with sidings and out-going and in-coming branches, all of which may be used at one and the same time.

Switch for Overhead Electric Conductors, J. Kuehnle, 451,696. Filed Dec. 18, 1890.
A switch or "frog" for use at a junction of one trolley wire with two others.

Electric Car Lighting Apparatus, B. J. Jones, 451,782. Filed Oct. 7, 1890.
A lighting apparatus for street cars. When the head-light is placed in position it automatically switches out the platform lamp at its end of the car, dispensing with the use of independent switches for that purpose.

Conduit System for Electric Railways, W. H. Ford, 451,815. Filed Oct. 8, 1890.
A bare conductor is made up in sections of a predetermined length; two mechanical contact devices or trolleys are fixed upon a vehicle at a greater distance apart than the length of a single section of the bare conductor; one of the trolleys is for electrical contact and the other is for the mechanical work of connecting and disconnecting with each section of the conductor successively.

Telegraphs:—

Telegraph Repeater, A. C. Booth, 451,449. Filed Aug. 24, 1889.
An automatic repeater for Morse circuits.

Telephones and Apparatus:—

Telephone Receiver, W. S. Corwin, 451,634. Filed Nov. 30, 1888.
Combines a permanently magnetized steel casing or tube, forming the handle, and a soft iron core or centre rod, insulated from the case at its rear end, with a diaphragm and bobbin or electro-magnet of the usual construction.

MINNEAPOLIS, MINN.—In the $15,000 damage suit of August Johnson again the Northwestern Telephone Exchange Company, Judge Smith directed the jury to return a verdict for the defendant, holding that the company was not responsible for the damage caused by the falling of the wire-laden pole, when some one, not connected with the company, had cut the guy ropes holding it in place. The case will probably be appealed.

Literature.

Decorative Electricity. By Mrs. J. E. H. Gordon. *Chas. Scribner's Sons.* New York, 1891. Illus. 178 pages, 9 x 5¾. Price, $3.75.

A MOST original and attractive book is this, written with an enthusiasm in behalf of the electric light that is most delightful and refreshing. Mrs. Gordon not only has all the pioneer spirit of her well-known husband, but positively "goes him one better." She has seen at a glance how many are the new opportunities for effective interior illumination afforded by the electric light, and has in an exceedingly clever and thorough manner worked all these possibilities out in practice. Each part of the modern House Beautiful, or of Philistine Villa, is taken, and all its requirements in the matter of light are dealt with in detail. Mrs. Gordon tells of her own experience in getting just what she wanted, and the book abounds in shrewd hints and suggestions. Thus we have methods worked out for a newspaper table with lamp; a summer fireplace with electric lights; bed reading lamp; kitchen grate light, as well as the more ordinary and commonplace lights for the living rooms, library, bath room, etc. If Mrs. Gordon's ideas were carried out, the perfection of lighting in our parlors and dining rooms would be reached. We should be conscious of agreeable illumination, but never find the lamps obtrusive.

We could heartily wish that this book, with its admirable two-score illustrations by Mr. Herbert Fell, might find its way into the hands not only of our designers of glassware and fixtures for electric lighting, but of every central station manager who has begun to supply lights for residences. It is a book that any superintendent can read with direct benefit, while he could not possibly put it in a customer's hands without experiencing an indirect but very substantial addition to the demand for current.

When Mrs. Gordon gets out her next edition, as she soon will, if we have not greatly misjudged the need existing for such a book, she may find it worth while to extend its scope and include other details to which the word "decorative" could hardly apply. Thus, in one instance a sleepless friend of ours has an arrangement by which he can light up the face of a clock at any moment during the weary hours of the night. In another instance the little lamp has been turned into a very comforting foot warmer for the bed. Mrs. Gordon makes incidental reference to electric hair curlers, but these are only one of a score of new devices in which electric heating begins to assume value and importance.

Mr. Gordon contributes a pithy little chapter on "Fire Risks," showing how safe the light is, properly installed. It is a great pity somebody did not add an index.

Electricity: The Science of the Nineteenth Century. By E. M. Caillaird. New York: *D. Appleton & Co.*, 1891. 7¼ x 5. 310 pages.

This is a modest book, and one for which there may not exist any very special need; but for all that it deserves commendation not only as being the work of a woman, but as a clear and intelligent exposition of the subject. In one sense it is popular, but the author has aimed, on every page, to be exact in phraseology and definition. The book is divided into four sections: Static Electricity; Magnetism; Current Electricity; Practical Appliances of Electricity, with a concluding chapter "What is Electricity?" and a "Note on the Polarization and Magnetization of Light." Each of the topics is handled with delicacy and sureness of touch, and the whole is interesting in style and treatment. Not the least merit of the book is that one is presented with the latest thought and theory in each branch of the subject. It has, moreover, enjoyed a revision by Prof. Ayrton, and has an index that will stand trial.

American Electrical Directory, 1891. Sixth year. *Star Iron Tower Co.*, Fort Wayne, Ind., 594 pages, cloth. Price, $5.

This sixth edition of a standard publication keeps up a high degree of merit and usefulness. It gives full data as to all the central stations and electric railway plants of the country, as well as those of Canada and Mexico. It also gives a list of the various manufacturing companies, in addition a list of all the State Electric Lighting Associations. Other sections contain the electrical societies and clubs of the country. A valuable feature also is that which contains the rules and requirements of the Boards of Fire Underwriters. In regard to all the companies and bodies, the names are given of all the officers, while there are full details as to the capitalization of each company and the nature of its central station, or electric railway equipment. Two other important sections are those devoted to insulated incandescent plants and to plants on steamboats.

In view of the diffiulties attendant upon the collection of matter of this kind, the amount of information furnished is remarkable, and its general accuracy is no less commendable. At the end of the book will be found the Philadelphia lighting schedule, and a number of tables and formulæ specially selected with an eye to the needs of station superintendents and managers. The book is well printed in bold type and strongly bound.

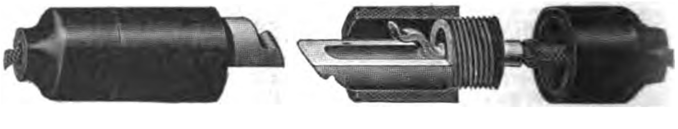
Patent Notes.

ELECTRIC RIVETING INTERFERENCE DECISION.
THOMSON vs. RIES.

A decision has been rendered by the Examiner of Interferences, in the United States Patent Office, in which priority of invention of the broad art of electric riveting and also of the apparatus for practicing this art, was awarded to Mr. Elias E. Ries of Baltimore, the other party to the interference being Prof. Elihu Thomson. The interferences just decided were two in number, the first being between the patent of Elihu Thomson, No. 396,015 dated January 8, 1889, for a method of electric riveting, and an application of Elias E. Ries, that was pending in the Patent Office at the time this patent was granted. The second interference was between a patent of Elias E. Ries, No. 403,374, granted May 14, 1889, and an application of Elihu Thomson filed June 14, 1889, for apparatus for electric riveting. As the records of the Patent Office show that Mr. Ries was the first to file his application for letters patent and that he had two applications. describing and claiming the inventions in controversy, awaiting official action at the time the Thomson patent was erroneously issued, Prof. Thomson was made the junior party in each interference. Testimony was taken by both parties, which showed that Mr. Ries was not only the first to file, but also the first to reduce the inventions to practice, and upon these and other facts brought out by the testimony the decisions awarding priority to Mr. Ries were based.

A NEW TRAILER CONNECTION.

THE devices commonly used for connecting the lighting circuits on the motor and tow-cars in electric railways, have projecting metal ends. As these are always connected to the circuits, a person standing on the ground or on a wet platform is apt to get an unpleasant shock by touching them. Most of the connections now on the market are, it is also claimed, much larger and heavier than their purpose demands.



A NEW TRAILER CONNECTION.

Our cut shows the new form designed by Mr. Chas. G. Armstrong, of Chicago, which has many good points. The two parts are interchangeable and the projecting metal tips are in circuit only when the whole is slipped together, when the parts are separated, these ends are dead and may be handled with safety even in wet weather The end of each conducting cord is soldered into a brass tube, and a knot in the cord takes all the strain off this joint. The contact surfaces are large and a stiff spring ensures a quick make and break. The insulating bushings, as well as the shell, is made of hard rubber, nicely finished. The whole is not much larger than the cut, and is well made throughout. George Cutter is putting it on the market.

NEW YORK CITY.—At the annual meeeting and election of the N. E. Telephone and Telegraph Co. the following officers were elected: President, Thomas Sherwin; vice-president, H. S. Hyde; secretary, D. W. Leedom; treasurer, W. R. Driver; executive committee, J. E. Hudson, M. G. Parker and Thomas Sherwin; general manager, J. W. Keller; auditor, S. W. Leedom; board of directors, F. Ayer, L. F. Beckwith, J. H. Cahill, J. P. Davis, B. C. Dean, W. H. Forbes. E. W. Beel, J. T. Hudson, H. S. Hyde, J. Jameson, J. Kavanagh, E. P. Meany, M. G. Parker, S. Salisbury, W. D. Sargent, and T. Sherwin. The report of 1890 shows the company's gross earnings, $1,383,667; expenses, $1,045,037; net earnings, $338,630.

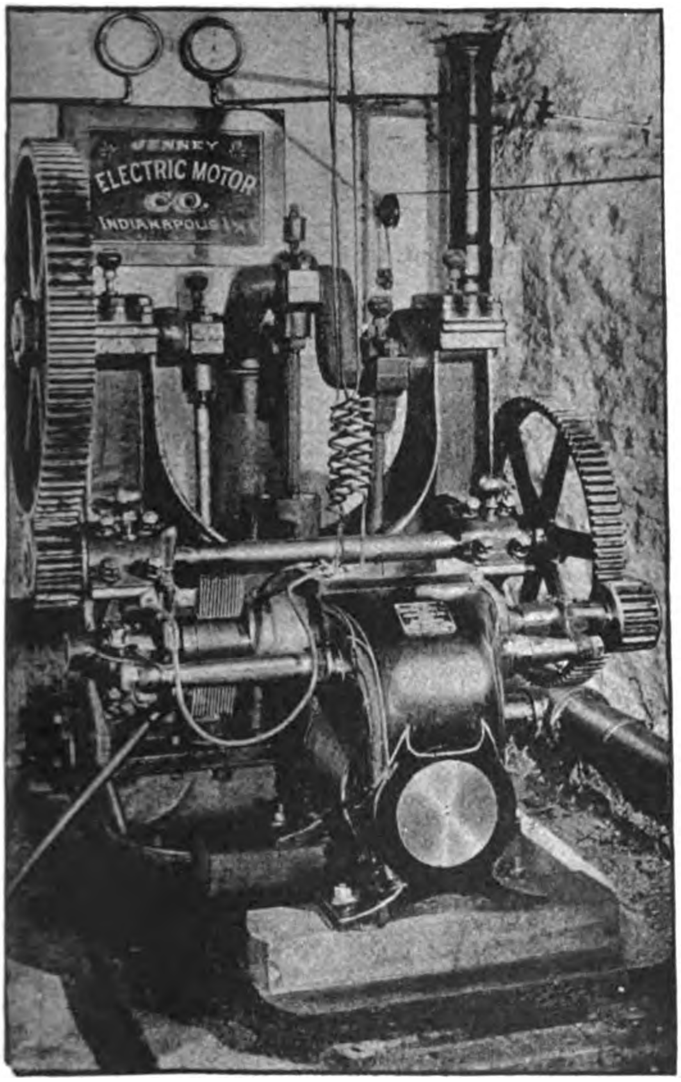
TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

Steady advertising and a growing trade go hand in hand.

"JENNEY" MOTOR APPLIED TO A HYDRAULIC PUMP.

An important application of the electric motor is that of pumping water, especially for operating hydraulic elevators. A notable instance of this kind is illustrated by the accompanying cut. A 7½ h. p. Jenney motor is shown geared to a Gould triplex pump at the Board of Trade Building, Indianapolis. City water had been used to operate the passenger elevator, but it was found that quite a saving in expense could be effected by sinking a well, putting in motor and pump in basement, and placing a tank on the roof.



Jenney Motor and Hydraulic Pump.

The combination has been working successfully for several months, furnishing ample water for the passenger elevator as well as for use throughout the building. The motor requires very little attention, and is much more desirable than a steam plant for the same work, as there is no heat, dust, noise, or danger of explosion. It is started and stopped automatically by means of a special switch which is operated by a float in the tank. The small pinions are of rawhide, and the bearings on motor are self-oiling.

These combinations apply equally well to roof or to pressure tanks, for elevator work, and are very effective for such work as draining of mines. The operation of this plant has been satisfactory from the start and is worthy of special notice on account of the very considerable saving in expense.

A REVOLUTION IN THE WIRE TRADE.

One of the most striking and important departures in the insulated wire business is that just made by the New York Insulated Wire Co. of 649-651 Broadway. It consists in nothing less than the opening of a large establishment of its own in Chicago, where a fine store has already been secured at 78, 80 and 82 Franklin street. The plan has been maturing quietly for some time, under the hands of secretary Gallaher and his associates, and the past month has witnessed some quiet, effective work in Chicago by President Place and Mr. J. W. Godfrey, the general manager. The company is the first concern of the kind in the country, we believe, to handle its trade in this manner, and thus meet purchasers as closely and promptly in Chicago, and the territory covered by that city, as if they were dealing direct with the New York house.

The new store which will be in readiness by May 20, is excellently situated with reference to the electrical industry of Chicago. It will have a fine suite of offices on the first floor fronting on Franklin street, and will occupy also the whole second floor. As this is 60 by 80 feet and is double decked, being very lofty, there will be available as much as 9,600 square feet of space on that floor alone. The store will carry a stock of about $100,000 worth of Grimshaw white core, "B. D.," "Competition" line wire, tapes, compounds, etc., and half the stock has already been shipped, the remainder following as quickly as possible.

In order that this store and its important trade shall be in the best hands, the Company have placed it in charge of Mr. G. H. Meeker, who has been associated with the rubber business for a great many years, and has ably represented the Company for a long time. He is well-known in Chicago. He will have with him a full corps of assistants, and leaves immediately to take charge of the Company's new interests in the West. As might be expected, the faint rumors that have circulated as to the intentions of the Company have excited no little curiosity, and it is beyond question that this full and explicit announcement of their plans will be received with the utmost interest wherever wire is sold and used in America. Such a step not only speaks volumes for the popularity of the Company's products but shows an inspiring confidence in the stability and growth of electrical business as a whole.

THE SHORT GEARLESS MOTOR.

Mr. C. C. Curtiss, of the Brush and Short companies, while visiting the offices of The Electrical Engineer last week, alluded to the remarkable popularity that the Short gearless motor enjoyed on the score of its noiselessness, and pointed out how this fact took the point out of nearly all the arguments of the people in Brooklyn, who have been objecting to the introduction of the trolley system.

A recent test of the gearless motor made on the private track of The Short Electric Railway Company and also in the streets of Cleveland has demonstrated its high efficiency. Although the E. M. F. of the line was low the current taken was very small considering the service to which the motor was put. On a level, and at a voltage of 400 to 450, the ampere readings ranged from 7 to 15. On severe grade and curve work the amperes ranged from 35 to 50. but with a voltage at times of less than 300, showing that the true ampere readings should not have exceeded 20 to 30. At the end of the long and rapid run the motor was almost stone cold, the heat developed being very small. The remarkable current efficiency of the gearless motor is due to the fact that the wire on both fields and armature is large and the counter E. M. F. is obtained by working up the intensity of the magnetic field to a very high point.

The "Gearless Motor," of the Short Electric Railway Company is in fact meeting with universal commendation. Already the first factory order is completely pledged, and the Short Company is on the point of closing large orders which will tax the capacity of their shops for a long time to come. The first gearless motor has now entered upon its eleventh week of service with a remarkable record. Although subjected to the severest tests—tests which can never come upon it in ordinary street railway service, there has not been one particle of trouble with it from beginning to end; neither armature or field coil has burned out; the motor runs perfectly cold with high efficiency, and pulls heavy loads over severe grades with entire ease. The motor has enormous reserve power, and it is practically impossible to burn it out. Motors of the first factory orders are beginning to come out and will be placed on regular service by May 15th, when the Short Company proposes to demonstrate to the world its ability to make an absolutely successful gearless motor, simple, efficient, and strong, perfectly protected, thoroughly reliable and "Standard" in street railway service.

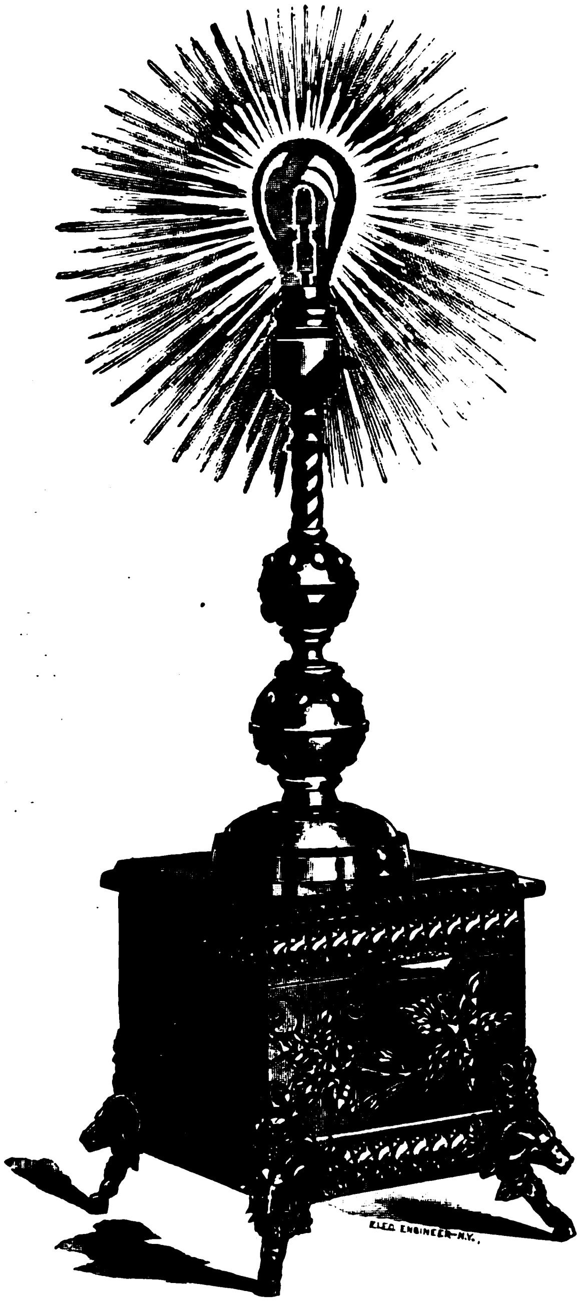
The Short Electric Railway Co. have the services of Mr. Paul W. Bossart, and have now added Mr. R. C. Carhart to their forces.

The Mason Battery and Electric Co. has been incorporated at Newark, N. J., to manufacture electrical appliances, batteries, etc.

THE CROWDUS PRIMARY BATTERIES.

In a recent issue of The Electrical Engineer[1] we described the interesting construction of the cell adapted by Mr. Walter A. Crowdus, electrician of the Crowdus Chemical-Electric Company, of Memphis, Tenn., by which connection from one cell to another in a series was effected without carrying over conductors above the cells, an arrangement which is always troublesome and liable to cause short circuits. As described at that time, connection from cell to cell is made by permanent conductors carried in the lower compartment of the cell free from all disturbing influence.

The Crowdus Company are now manufacturing a series of such cells, one of which is illustrated in the accompanying engraving. The smallest of these, Type 4A, has a capacity of 120 watt hours and is designed for a normal discharging rate of 5 amperes at 5 volts pressure. The cell on open circuit gives 7½ volts and is capable of delivering 25 amperes on short circuit. Type B, has a capacity 140 watt hours, and type 4C, Fig. 1, of 190 watt hours with a normal discharge rate of 7 amperes at 5 volts.



ELEC. ENGINEER-N.Y.

Fig. 2.—The Crowdus Ornamental Battery Lamp.

The positive element in the cell is zinc. The solution is composed of a mixture of 3 pints of water to 4 pints of sulphuric acid, mixed to saturation with nitrate of soda. The tops of the cells are covered by a rubber pan containing peroxide of manganese, which absorbs all the gases given off by the cell, so that its presence in a room is not objectionable. **The nitrate of soda is sent out in the shape of a white salt, which is added to the sulphuric acid solution in the manner stated above. These batteries are built for powerful and constant service and are not intended to remain on open circuit for any great length of time. Should they be required to do intermittent work, however, it is more economical** to use a solution of common salt with the zincs, in the place of acidulated water. These cells are built in a variety of sizes for a wide range of work, such as the lighting of table lamps, the driving of small motors, etc. A design of a table lamp is shown in Fig. 2, in which the battery is contained in the base of the lamp, the base being only 7 inches square.

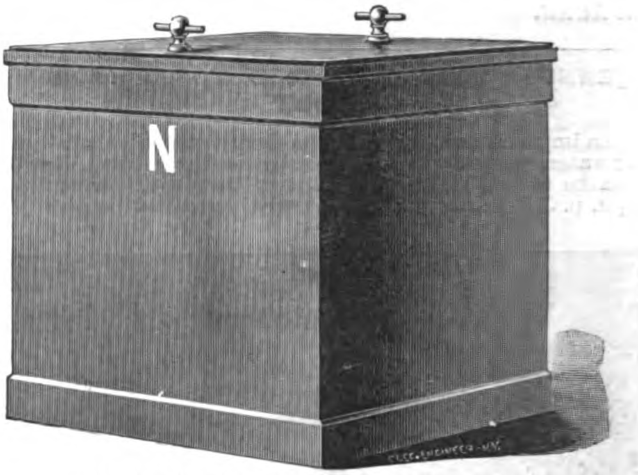


Fig. 1.—The Crowdus Primary Battery.

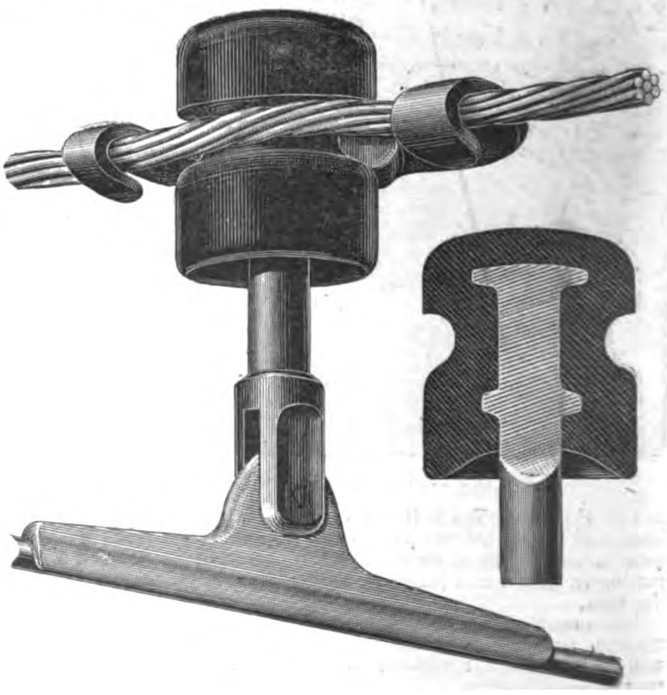
THE "CINCH" INSULATOR.

The "Cinch" trolley wire insulator, shown in the accompanying illustration, has many distinct advantages, which have won for it the unqualified approval of every practical man who has seen it. The insulating material is comb stock rubber, the stem and yoke are of malleable jet iron, and the pin is of brass. The strains on the insulating material are solely those of **compression. There are no screw threads, or other parts subject to deterioration from exposure. The wire pin is more perfect in its details than any similar pins that have heretofore been introduced. The objects aimed at in the design of this insulator are, great strength, high insulation, small size, convenence, durability and cheapness. This insulator is manufactured by Messrs. Emmet Bros. & Griswold, 150 Broadway, New York, who will send samples free to any one wishing to examine it.**



The "Cinch" Trolley Wire Insulator.

---

[1] The Electrical Engineer, April 22, 1890.

PAPER INSULATION FOR ELECTRIC LIGHT AND TELEPHONE PURPOSES.

One of the most important strides in the matter of insulation of cables for powerful electric light currents has been made within the last three or four years. Many materials have been tried and found more or less wanting. The mechanical and electrical requirements of a 10,000 volt conductor of the present day are very exacting. The cable must be light and flexible; it must be strong enough to withstand the strain, and wear and tear of reeling and unreeling and hauling through crowded conduits without exposing the insulation to damage. The insulation must be high at normal temperatures, so as not to fall too low when exposed to excessive heat, and it must further be able to retain its power of preventing a breakdown or blow out even when the insulation has fallen very low from such exposure.

The Norwich Insulated Wire Co., of this city, claim that these requirements are met absolutely in their cables, in which paper is employed as the insulator. This company are working night and day to meet the demand for their cables, which is chiefly for No. 6 B & S wire leaded cable, outer diameter ⅝ inch. Some twenty-five miles of this cable is now being laid in New York alone, and in Chicago over thirty miles have been laid, whilst orders have been filled for England, France and Germany, including a very large sectioned 10,000 volt concentric Ferranti cable. The company has yet to receive its first complaint of a break down, although their cables have been laid and jointed by the lighting companies' regular cable men, who use their own way of jointing, the company finding it unnecessary to recommend any special method.

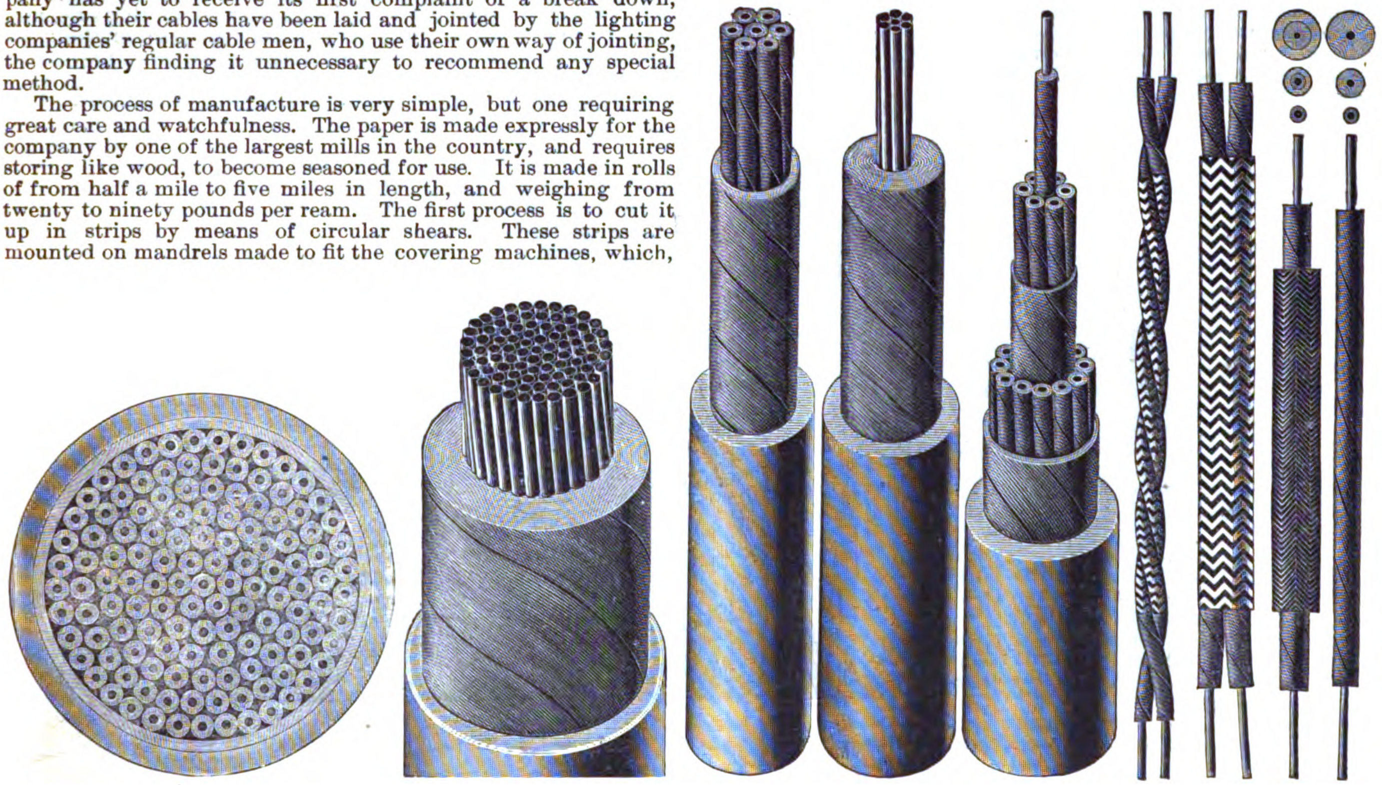
The process of manufacture is very simple, but one requiring great care and watchfulness. The paper is made expressly for the company by one of the largest mills in the country, and requires storing like wood, to become seasoned for use. It is made in rolls of from half a mile to five miles in length, and weighing from twenty to ninety pounds per ream. The first process is to cut it up in strips by means of circular shears. These strips are mounted on mandrels made to fit the covering machines, which, revolving at from 60 to 500 turns per minute, according to the size of the conductor, lay the paper on it in overlapping spirals.

As with every spiral laid on, the cable is passed through closely fitting dies, the result is a very hard, dense, compact and flexible covering, very difficult to damage or abrade and at the same time one of exceedingly uniform diameter. The layers of paper are laid on with their spirals alternately in opposite directions.

After covering to the requisite thickness the cable is wound on open iron reels and placed in drying ovens where it is exposed to a temperature of about 250° F., until all the moisture is thoroughly expelled. Then, while still hot, it is submerged in compound, which is maintained by steam coils at a heat of some 270° to 280° F, for a length of time depending on the thickness of the insulation or other electrical requirements. The nature of this compound is a close secret. It is then passed directly from the tanks through the hydraulic press which puts on the lead covering. The machinery by means of which the lead is laid on the cable in one continuous length, was designed and constructed under the patents of Mr. J. Draper Bishop, the electrical engineer of the company.

The cables are then tested, when necessary, at a potential of 2,500 volts for insulation, as well as for conductivity and capacity.

The insulation is always high, exceeding on an average 2,000 megohms at 75° F.



Telephone Conf. Cable. Power. Power. Arc. Telephone. Leads.

Paper Insulated Electric Light and Telephone Cables and House Wiring Conductors.

Some of the performances of these cables are remarkable. Lengths of 1,000 feet were submitted to one of the largest electric light companies for the purpose of being tested to "break down." They successfully resisted a strain of nearly ten thousand volts and were finally left intact. The cable was then placed *in boiling water* and kept submerged for *forty eight hours*. While still in the tank it resisted a potential of nearly eight thousand volts before failing.

One most important advantage possessed by these cables is, that, no matter how rough a treatment the cable may be submitted to, even to destroying the lead and rupturing the insulation, the conductor will always remain absolutely concentric. The insulation is uniform throughout every inch of its length and cannot by any accident of manufacture or subsequent treatment become thinner on one side than another, or, in other words, eccentric.

The Norwich Insulated Wire Co. has also made a considerable quantity of telephone cables, over 5,000 miles of conductor being laid in New York alone. The capacity of these cables, when made to conference standard specification, has been reduced, during the past year, from 22 microfarad to below .08 microfarad per mile.

The company has lately increased its plant to a capacity of a mile a day of such cable. Its latest undertaking is the manufacture of paper insulated leads for incandescent house and office wiring.

Our illustrations show a variety of the products of this enterprising company, the officers of which are: Louis D. Beck, president; Anthony Dey, vice-president; E. D. McCracken, general manager. The offices are at 58 Cedar street, and the works at corner of Lorimer and Bayard streets, Brooklyn, N. Y.

THE BALL & WOOD CO.

A circular has been issued by the above company, of 15 Cortlandt street, announcing the fact that they are now prepared to build and furnish improved Ball automatic cut-off engines. Mr. T. C. Wood becomes the president of the new company; Mr. F. H. Ball, is vice-president and general manager; Mr. C. R. Vincent, is secretary and treasurer; and Mr. T. G. Smith, Jr., will be entrusted with the interests of the company, with his principal office at Cincinnati. The management point to the numerous contracts they have carried out with eminent success, and ask for support and patronage under their new régime. They are ready to receive and discuss proposals and give estimates on equipments of any size.

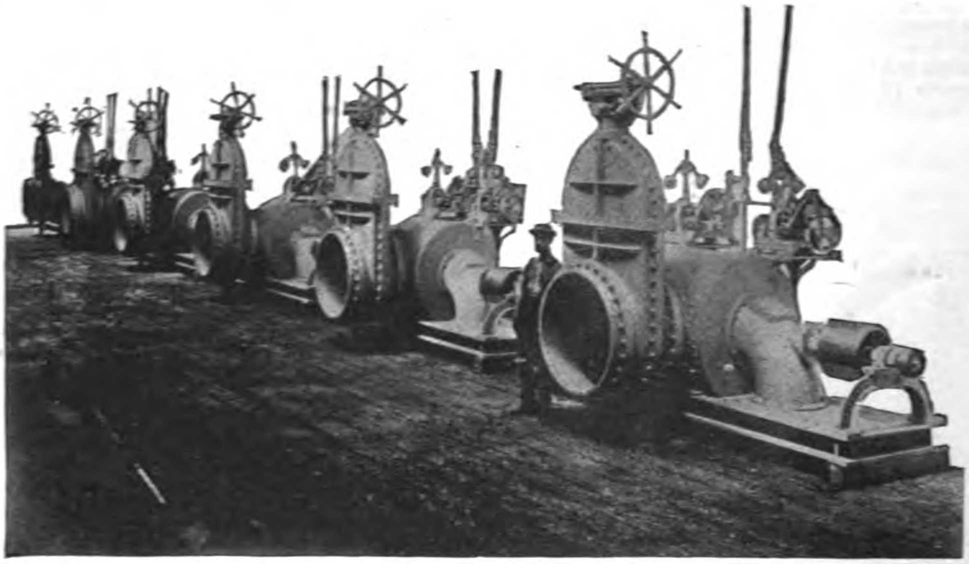
CLEVERLY AS A PATRON OF ART.

After complimenting his friends for a long time past and quite frequently with articles of the "bigotry and virtue" kind, such as calendars, thermometers, preserve dishes, etc., Mr. H. A. Cleverly, of Philadelphia, has hit upon the happy idea of presenting those whom he wishes to bear him closest in mind with a very handsome terra cotta alto relief portrait of himself. This portrait is set in a massive cocoanut frame, the husk of which is so broken as to make a fringe of hair over the cotta brow and a rim of beard around the terra chin. As a general thing, busts and plaques have a stiff, formal "in memoriam" look, but to make this of his as easy and lifelike as possible, Mr. Cleverly has placed a modest dudeen between the smiling lips. Mr. Cleverly may well be content to go down to posterity in this guise. In some of the alto reliefs, in order to make them more racy of the Philadelphia soil, a dainty touch of moss has been added to the frame.

THE STILWELL & BIERCE MFG. CO.

SINCE electrical transmission has so greatly increased the value of water power, the Stilwell & Bierce Mfg. Co., of Dayton, Ohio, manufacturers of the celebrated Victor turbine, are making a leading specialty of designing and installing complete water power plants for electrical purposes and are doing an extensive business.

As an example of some of their recent work, we illustrate in the accompanying engraving a line of 10-inch Victor turbines on horizontal shafts complete with flume, bed-plate, governors, etc., designed and built for the Edison Electric Illuminating Co., of Spokane Falls, Wash., for a special service. These turbines operate under 70 feet head, developing 186 h. p., and are arranged for driving two dynamos direct from the turbine shaft. The feeder is provided with a valve gate for shutting out water. Each turbine is entirely independent, being provided with a separate gate and governor, so that either one, or both, can be operated at will. While this pair of wheels was designed expressly for driving the two dynamos, it will be readily seen that similar designs can be adapted to a great range of work.



VICTOR TURBINES AT THE EDISON ELECTRIC ILLUMINATING CO.'S STATION, SPOKANE FALLS, WASH.

Six pairs of these turbines are supplied with water from one feeder, a branch extending to each pair. The same station has also a pair of 15-inch Victor turbines on horizontal shafts, equipped with disc friction pulleys; an arrangement which is very simple, compact and strong.

The catalogue of the Stilwell & Bierce Mfg. Co., illustrates a great variety of work of this kind, and is of especial interest, as it shows their ability to meet the requirements of peculiar and difficult locations.

UNIVERSAL ARC LAMP CO.

The above company, of 42 Broad street, this city, have appointed Mr. C. C. Sibley, their general manager. Mr. Sibley has sold out the electrical manufacturing business of C. C. Sibley & Co., to the Interior Conduit and Insulation Co., and has entered upon his new duties.

GENNERT'S COLORINE.

A great many central station men require colored incandescent lamps from time to time. An order comes in for special ball or banquet lighting, or perhaps for a wedding or reception. It doesn't seem good economy to have a lot of costly colored incandescents lying around the station, and so very often the chance to make extra earnings in this way is allowed to slip. We speak from actual experience and knowledge. Many managers have endeavored to meet the situation by getting up some artificially colored lamps for themselves—with preparations or dodges of their own. They have not always been successful. The E. P. Gleason Manufacturing Co., of Mercer street, this city, have had this matter forced upon their notice more than once, and have often been called upon to get up colored incandescents in a hurry for their central station friends. Quick as usual to meet a new want, the company have now placed on the market, through the ingenuity of Mr. E. F. Gennert, a preparation to which they have given the name of "Gennert's Colorine." It is made up in half-pint bottles that cost only fifty cents apiece, and can already be had in all the primary colors, of brightest hue. Each bottle will color 100 lamps thoroughly, and they will then stand exposure to weather or heat indefinitely. At the same time, the lamps can soon be made available again for ordinary every day duty, so that at no time need a manager carry a stock of lamps that are not earning something. Simple instructions go with each bottle. We have ourselves inspected some lamps treated in this way, and found them admirable. The preparation does not dim the glass and yet it sticketh closer than a porous plaster, refusing to come off even under the most vigorous application of the finger nail. We think the E. P. Gleason Manufacturing Co., have made another decided hit, and believe that "Colorine" will become as indispensable a part of a station outfit as lamps or engines or oil.

ELECTRIC MERCHANDISE CO.

During the last few months the above company, of 11 Adams street, Chicago, have received a number of orders from tramway companies in foreign countries, and have also received inquiries almost daily regarding the practical working of electric street railways in this country. This has led them to look into the matter carefully, and after correspondence with parties interested, they believe that foreign roads are ready to adopt at once, the electric railway system as used in this country, if the advantages can be fully explained to them. Mr. Frank X. Cicott, of the company, having spent some months last year travelling in Europe, also became convinced of this fact. Believing that it would be to their interest to be early in that field, they have decided to send Mr. Cicott as their representative to foreign countries, and he sailed on the Cunard "S. S. Servia," on Saturday the 9th inst. to spend probably two months in working up an interest in such matters. Such enterprise as this deserves more than passing notice, and will bring its own reward.

THE
Electrical Engineer.

VOL. XI. MAY 20, 1891. No. 159.

A VISIT TO THE CROCKER-WHEELER ELECTRIC MOTOR CO.'S FACTORY.

ALTHOUGH one of the newest of the arts, the designing and building of electric motors has now reached a stage of development which places them foremost in the ranks of prime-movers. The laws upon which such machines are designed have been laid down with accuracy sufficient to enable the competent electrical engineer to design a machine which shall, when constructed, vary but a small fraction from the calculations upon which its construction is based. But, as in every machine required for continuous use, and especially so in a prime mover, the mechanical design is a subject of no less important consideration. Among those constructors who have given probably equal attention to both these important qualities in a motor, are Dr. S. S. Wheeler and Prof. F. B. Crocker, and we think that, in view of the contemplated visit of the American Institute of Electrical Engineers, to the factory of the Crocker-Wheeler Motor Co., a description of their latest types of machines now being manufactured, together with the methods employed, will be of interest.

The company are now situated in an enlarged new shop, where the manufacture of their machines is carried on under the direct supervision of Dr. Wheeler, and special pains have been taken to make all parts to standard gauges, so that they may be interchangeable, for which purpose the best metal working tools have been procured. The accompanying illustration, Fig. 1, gives a general view of the machine shop, and Fig. 2 that of the armature winding room. The Crocker-Wheeler motors, throughout the entire range of sizes, are built up of a cast iron base plate, into which drop forged wrought iron magnets are inserted and which encircle an armature consisting of laminated wrought iron.

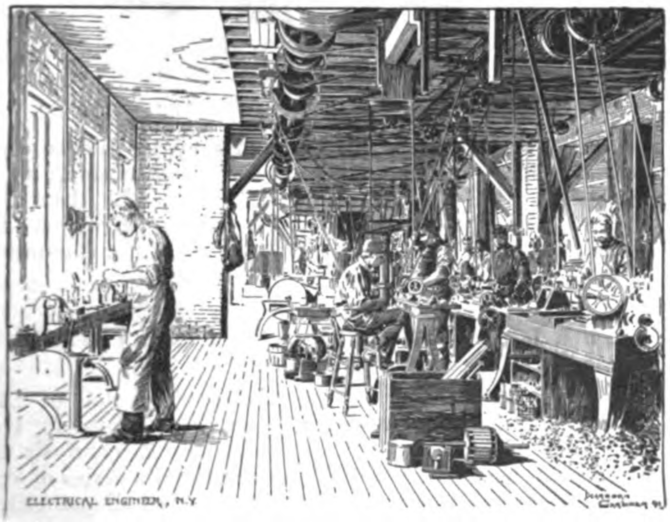

FIG. 1.—MACHINE SHOP; CROCKER-WHEELER MOTOR CO.

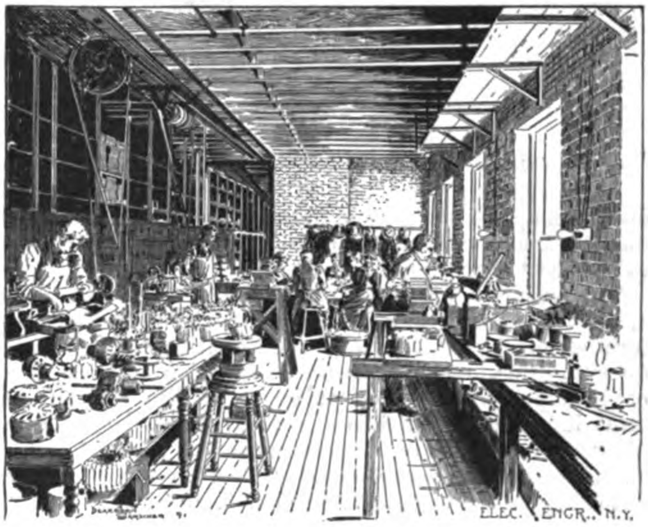
The latest form of armature adopted presents several points of interest. As will be seen in the accompanying illustration, Fig. 3, a toothed armature is employed, but the spaces *a*, instead of having their sides parallel, are trapezoidal, which construction, as will be presently shown, has several marked advantages. In the first place the increased surface afforded by the outer edge of the tooth, reduces the reluctance of the magnetic circuit, affording an easier path for the magnetic lines from pole-piece to armature, and vice versa. To this is added the fact that it holds the wire firmly in place and prevents its being thrown out by centrifugal force, while, at the same time, it protects it against mechanical injury. The outside of the teeth, being large, present an almost continuous surface to the pole-pieces, and, as a consequence, the formation of Foucault currents is avoided, notwithstanding the fact that the pole-pieces are solid. Were this not the case the pole-pieces would, as has frequently been demonstrated, require to be laminated.



ELEC. ENGR., N.Y.

FIG. 2.—ARMATURE ROOM; CROCKER-WHEELER MOTOR CO.

The trapezoidal form of slot, it will be noticed, corresponds exactly to the natural forms of the sections on the inside of the Gramme ring, thus securing a symmetrical winding and economizing space. It will also be noticed that the pole pieces are brought farther around the armature on the side away from the field coils T T than on the the other side *t t*, by which the tendency to a greater magnetic pole on the side nearer the coils is counteracted. The armature is built up, as will be seen, of two half sections A A, upon which the windings are wound and which are then joined together by means of bolts B B.

Another improved method of construction has been adopted, as a result of which the machine work done on the motors is largely reduced. Heretofore it has been customary to assemble the magnetic skeleton of the machine and to bore out the pole pieces to conform to the space occupied by the armature. The method adopted by the Crocker-Wheeler Company simplifies this construction and obviates the necessity of boring out the field poles. As already stated, the field magnet cores, together with their pole pieces, consist of single drop forgings. Two of these forgings are placed around a dummy armature and the whole is then clamped in a jig, whereupon the base of the machine is bored and the ends of the magnet cores are trimmed to shape so that, when inserted into the base and the dummy armature withdrawn, the magnet cores will occupy exactly the position intended.

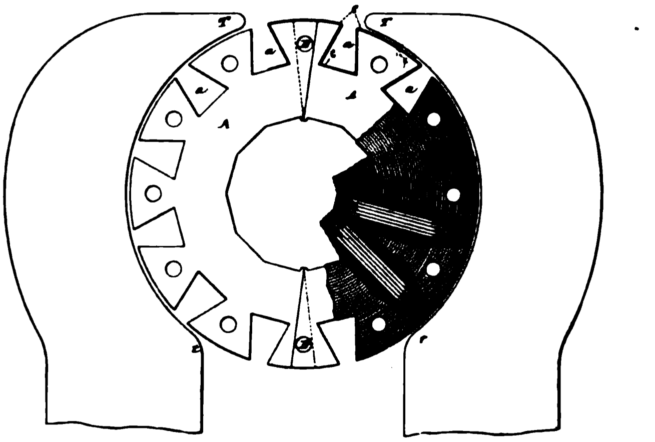


FIG. 3.—NEW CROCKER-WHEELER ARMATURE.

The machines are assembled in the shop shown in Fig. 4, and thoroughly tested in the shop shown in Fig. 5, before being sent out. One of the excellent features introduced on these machines is the designation, on each, of not only the power and speed at which it is to run, but also other information which is of value, not only to the manufacturer, but to the user; thus on the end plate of each armature of the half horse power 500 volt motor we note the following: 24 sections, 177 turns, No. 29 wire.

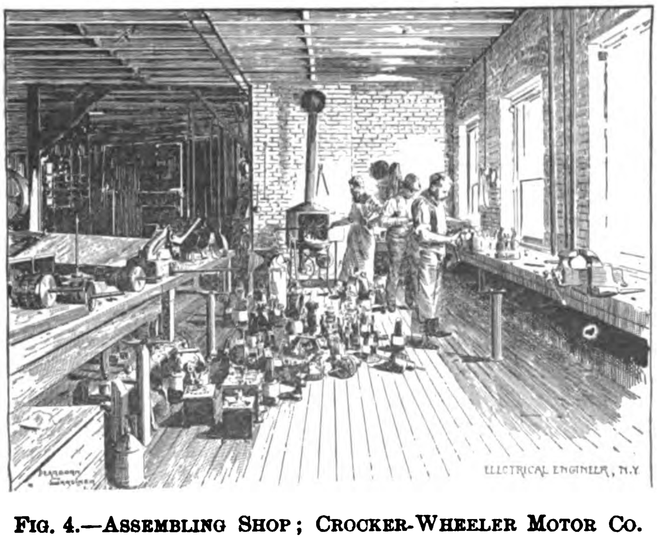

FIG. 4.—ASSEMBLING SHOP; CROCKER-WHEELER MOTOR CO.

The machines, the general type of which is now well-known, are built in 8 sizes, ranging from $\frac{1}{16}$th h. p. to 5 h. p. The smallest machine has a spider which grips both sides of the armature ring and thus gives a firm connection, while on the larger machines, the armature is secured to a face plate by bolts running through the armature teeth. All the machines are built with self-oiling boxes, so that they require no attention for weeks at a time. The trouble frequently experienced with copper brushes has also been obviated by the introduction of a special kind of carbon brush, which, besides making good contact, has very high lubricating qualities and leaves the commutator smooth.

With machines of the larger type are provided regulator boxes, all of which are constructed without wood; slate and iron alone being employed for the tops and sides, and the rheostat coils are designed to carry the full current for prolonged periods without heating. These boxes are so arranged that the throwing of the switch first closes the circuit through the field, energizing the magnets, after which the armature is thrown in circuit so that it at once generates a counter E. M. F. and starts at full power, but without the heavy rush of current.

Besides the constant potential machines of all sizes and for all potentials built by the company, they also manufacture arc motors, a new type of which will shortly be brought out, and the regulation of which is effected in a remarkably simple manner. One of the latest adaptations of the Crocker-Wheeler motor is called the LaRue combination, which consists of a ventilating fan and motor mounted in the same iron frame and affording a very compact installation.

The machines of the Crocker-Wheeler Motor Company throughout their varying sizes have each been separately designed for their stated powers, and may be said to embody the most modern principles of construction, both electrically and mechanically. We may add that the Thomson-Houston Electric Company have arranged to secure from the Crocker-Wheeler Electric Motor Company all motors under 2 h. p. required by them.

FIG. 5.—TESTING ROOM; CROCKER-WHEELER MOTOR CO.

ELECTROLYSIS APPLIED TO QUALITATIVE ANALYSIS.

At a recent meeting of the Liverpool Section of the Society of Chemical Industry, a paper was read by Dr. Charles A. Kohn, on the "Application of Electrolysis to Qualitative Analysis." Dr. Kohn described a series of experiments he had made on the detection of small quantities of the mineral poisons, antimony, lead, mercury, and copper, taking advantage of the quantitative electrolytic methods of analysis, an account of which he had given to the society on a previous occasion. The methods were very delicate, clean, and decisive, and likely to be of value in cases of medical and of medico-legal inquiry. Very small quantities of silver and of gold could also be detected electrolytically with ease, and the methods had the further advantage of being made approximately quantitative when desirable.

A NEW METHOD OF MEASURING INSULATION RESISTANCE.

BY

Geo. W. Patterson, Jr.

The usual methods of measuring insulation resistance, having failed to give satisfactory results when used in testing a sample of insulated wire, it became necessary to seek for another. The method which was finally used has certain resemblances to two others, namely, the direct deflection and the fall of potential methods, which are well known; but as it avoids the principal fault of each of these methods, at least when applied in this case, it seems original enough to be worth communicating.

The fault of the direct deflection method is that, if the wire has an insulation resistance of, say, over a hundred thousand megohms, it is very difficult, using an electromotive force of less than several hundred volts, to obtain a galvanometer which is at the same time both sensitive enough to give a large deflection, and stable enough to give a constant zero reading. The fault of the second method is, that an insulated wire of even short lengths, if connected with a source of electricity, will go on increasing its charge for several minutes at a considerable rate and sometimes for even an hour at a measurable rate. This increment does not increase the apparent charge; for part of the charge has become, for the time being, latent. It is said to be absorbed. This absorbing goes on even after the source of electricity is removed. A charge, once absorbed, is not readily given up; consequently a wire will appear to have leaked all that has been absorbed between the time its charging ceases and the time it is discharged.

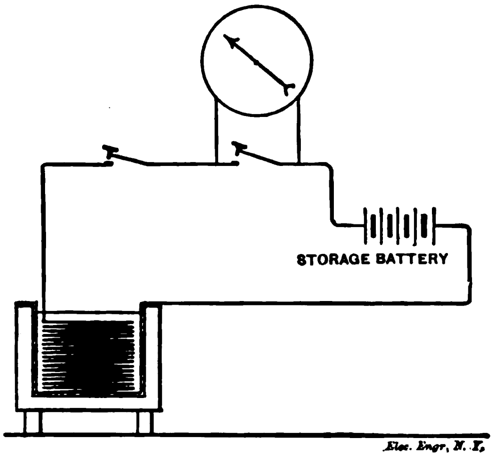

Fig. 1.—A New Method of Measuring Insulation Resistance.

The sample of insulated wire, the subject of the experiment, was one thousand (1,000) feet in length, and No. 18 B. & S. gauge. In the course of the experiment it was found to have an insulation resistance of about ninety thousand (90,000) megohms and a capacity of about eighty-two thousandths (0.082) of a microfarad. In order to insure its being well wet, it had been kept for several months in the tank of water in which it lay during the experiment.

The two methods which were first used and which proved unsatisfactory, were as follows:—In the former, the direct deflection method, the wire and the lining of the tank were connected with the terminals of a storage battery of 62.5 volts E. M. F., through a Thomson astatic galvanometer of 6,656 ohms resistance, and keys which allowed the cutting out or the reversal of the galvanometer, as well as the making or breaking of the main circuit. The galvanometer, which was read by means of a telescope and scale, was about as sensitive as one could make it and still feel confident that the zero would remain unchanged. For convenience the telescope and scale were put at such a distance that each millimetre of the scale corresponded to a thousandth (0.001) of a microampere.[1]

While the wire was charging, the galvanometer was cut out; after a few seconds it was again thrown into circuit, and when the needle came to rest, the steady deflection was read. Reversing the galvanometer gave a deflection in the opposite direction. The mean deflection was taken. As the needle was somewhat unsteady, it was difficult to read the deflection to within a tenth. As nearly as the reading could be made, it was about 0.7 mm. This would indicate a current of about 0.0007 of a microampere, there being, as before, a possible error of one part in seven. The insulation resistance is obtained by dividing E. M. F. by current. In this case it was, within one part in seven, 90,000 (90,000 ± 13,000) megohms.

The uncertainty of the result being so great, the second method was then tried. This was the well-known loss of charge method. It may be briefly described as follows:—First, the capacity of the wire is measured and then it is charged for some definite period and immediately discharged through a ballistic galvanometer. It is then recharged as before, but, instead of being immediately discharged it is insulated for some suitable period, in order that part of the charge may be lost; after the period has elapsed it is discharged through the galvanometer. The ratio of the two readings is the same as the ratio of the E. M. F.'s at the beginning, and at the end of the period of insulation. Dividing the length of the period (in seconds) by the product of the capacity and the Napierian logarithm of the ratio of the potentials, gives the insulation resistance

$$R = \frac{t}{C \cdot \log_e \left(\frac{V_0}{V_t}\right)}. \qquad [1]$$

Several different lengths of the periods of charging and of insulation were taken. Calculating the insulation-resistance by equation [1], various results were obtained. They were, on the average, not greatly different from the result previously obtained; but as they differed among themselves, by fully fifteen thousand megohms, it was evident that this method was, in this case, no more satisfactory than the previous one. These variations in the result are doubtless due to absorption.

Neither determination being considered sufficiently accurate, it occurred to me that the first method might be so varied as to avoid the small readings and still use no greater E. M. F. The variation consisted in charging the wire and, having insulated it, to allow the leakage to go on unreplaced for a suitable period of time and then to measure the quantity of electricity which was needed to charge the coil as before; for, although the deflection of the galvanometer was too small to be accurately read, if the leakage from the wire was continuously replaced, yet when the leakage for a period of even a few seconds was replaced in an instant, the throw of the needle became considerable. In order to simplify the calculation, a ballistic galvanometer was set at such a distance from the telescope and scale that each mm. of deflection corresponded to one-thousandth (0.001) of a microcoulomb. The constant of any ballistic galvanometer is obtained by dividing the quantity of electricity producing the throw of the needle, by the number of scale divisions of the deflection. The quantity of electricity is measured by the product of the capacity of the condenser and the E. M. F. of the cell used. In this case we used a Carhart-Clark standard cell of 1.440 volt E. M. F. to charge an Elliott condenser of one-tenth (0.1) of a microfarad capacity. The condenser was then discharged through the galvanometer, giving a reading of

---

[1] One million microamperes equal one ampere.

144 mm. Or, expressing the constant in the form of an equation,

$$K = \frac{V_{s.c} \, . \, C_1}{D_1}, \qquad [2]$$

where $V_{s.c}$ = the E. M. F. of the standard cell; C_1 = the capacity of the condenser; and D_1 = the reading of the galvanometer.

K is also equal to $\frac{Q_2}{D_2}$, where Q_2 and D_2 are any quantity of electricity and the corresponding deflection, respectively. Therefore

$$Q_2 = \frac{D_2}{D_1} \, . \, V_{s.c} \, . \, C_1. \qquad [3]$$

The wire was then connected with the storage battery as first described [Fig. 1], and to insure its becoming fully charged, was left on closed circuit for half an hour. Next the galvanometer was introduced into the circuit, and at some carefully noted time, the circuit was broken. After a certain period, say, thirty seconds, the key was closed for an instant and the throw of the galvanometer was noted. After another like period a second reading was taken, and so on for a considerable time. It may be remarked here that the fall of potential is so slight in short periods, that the deflections are, within the limits of errors of observation, proportional to the length of the periods; consequently, even if there should be large variations in the lengths of the separate periods, the summation of the readings for, say, five minutes will remain practically a constant. This constant for five minutes was found to be within two of two hundred and ten (210 ± 2), which would make the value for a period of thirty seconds within two-tenths of twenty-one (21 ± 0.2).

It was noticed that if the readings were begun before the charge had become practically a maximum, that the readings were somewhat larger, but became rapidly less, and in the course of half an hour had almost reached their minimum. If considerably longer periods were chosen, it was noticed that there was a perceptible falling off even after an hour; but for the shorter periods of thirty seconds this falling off was not noticeable after half an hour.

The usual formula for rate of loss of charge is

$$\left(\frac{d\,Q}{d\,t}\right) = \frac{V}{R}, \qquad [4]$$

where $\left(\frac{d\,Q}{d\,t}\right)$ is the first derivation of the charge with respect to the time, and V and R are the E. M. F. and the insulation resistance respectively. If, during a time t, the change in the value of V, $[V_o - V_t]$, is so slight as to be negligible, then

$$\frac{V_o}{R} \pm \frac{Q_o - Q_t}{t}, \qquad [5]$$

when the subscripts o and t denote, respectively, immediately after charging and after a further time t.

If D_2 is the deflection produced by the quantity $(Q_o - Q_t)$, then

$$Q_o - Q_t = D_2 \, . \, K; \qquad [6]$$

consequently, by equations [2], [5] and [6],

$$R = \frac{D_1 \, . \, V_o \, . \, t}{D_2 \, . \, V_{s.c} \, . \, C_1}. \qquad [7].$$

Taking the average reading for thirty seconds to be within two-tenths of twenty-one [21 ± 0.2] mm., we have in this case

$$R = \frac{144 \times 62.5 \times 30}{(21 \pm 0.2) \times 1.440 \times 0.1} = [89{,}200 \pm 800] \text{ megohms.}$$

Should V vary during the time t, so as to cause error in the result, an average value may be taken. For all practical purposes we may take the mean of the highest and the lowest values $\left[\frac{V_o + V_t}{2}\right]$; but if an absolutely exact value is needed it is:—

Average value of V =

$$\frac{V_o}{1 + \frac{1}{2}\left(\frac{Q_o - Q_t}{V_o\,C}\right) + \frac{1}{3}\left(\frac{Q_o - Q_t}{V_o\,C}\right)^2 + \frac{1}{4}\left(\frac{Q_o - Q_t}{V_o\,C}\right)^3, \text{ etc.}}$$

This may be shown as follows:—

It is evident that $V_t = V_o - \frac{Q_o - Q_t}{C}$; dividing by V_o we have $\frac{V_t}{V_o} = 1 - \frac{Q_o - Q_t}{V_o\,C}$. By equation [1]

$$R = \frac{t}{C \, . \, log_e\left(\frac{V_o}{V_t}\right)} = \frac{t}{C\left[-\,log_e\left(\frac{V_t}{V_o}\right)\right]} = \frac{t}{C\left[-\,log_e\left(1 - \frac{Q_o - Q_t}{V_o\,C}\right)\right]}$$

Expanding the logarithms into a series gives

$$-\,log_e\left(1 - \frac{Q_o - Q_t}{V_o\,C}\right) = \frac{Q_o - Q_t}{V_o\,C} + \frac{1}{2}\left(\frac{Q_o - Q_t}{V_o\,C}\right)^2 + \ldots + \frac{1}{n}\left(\frac{Q_o - Q_t}{V_o\,C}\right)^n + \text{ etc.}$$

Substituting and simplifying

$$R = \left[\frac{t}{Q_o - Q_t} \times \frac{V_o}{1 + \frac{1}{2}\left(\frac{Q_o - Q_t}{V_o\,C}\right) + \frac{1}{3}\left(\frac{Q_o - Q_t}{V_o\,C}\right)^2 + \ldots + \frac{1}{n}\left(\frac{Q_o - Q_t}{V_o\,C}\right)^{n-1} \text{ etc.}}\right]$$

Therefore by equations [2] and [6],

$$R = \left[\frac{D_1 \, . \, t \, . \, V_o}{D_2 \, . \, C_1 \, . \, V_{s.c}} \times \frac{1}{1 + \frac{1}{2}\left(\frac{Q_o - Q_t}{V_o\,C}\right) + \ldots + \frac{1}{n}\left(\frac{Q_o - Q_t}{V_o\,C}\right)^{n-1} + \ldots}\right] \qquad [8]$$

If the first two terms of the series are taken, the rest being neglected, it may be easily shown that the result is the same as if the mean between the highest and the lowest values of the E. M. F. had been taken and substituted for V_o in equation [7].

In the case of the wire on which these experiments were made, even the second term may be neglected, with an error of less than one third of the possible error due to irregularities in the readings, for

$$\frac{1}{2}\left(\frac{Q_o - Q_t}{V_o\,C}\right) = \frac{21 \times 0.001}{2 \times 62.5 \times 0.082} = 0.002048.$$

The next term of the series will be 0.000,006. Applying the whole correction R = [89,000 ± 800] megohms.

This method has also been used in testing another sample of a thousand feet of insulated wire, which after being in the water one day had an insulation resistance of about five hundred thousand (500,000) megohms. (The insulation-resistance has since fallen to about one-fifth of that amount. A final determination has not yet been made.) The first method applied to this was a total failure. There was no readable deflection of the galvanometer. On applying my method the deflections were quite large at first and decreased for several hours. After four hours they had fallen to about one third of the value, which they had twenty minutes after the charging began. There was evidently considerable absorption.

In presenting this method, I would call attention to what I consider its chief advantages over the more common methods. In the first place, supposing that the wire has sufficient capacity to admit of the use of the method, we may apply it in any case when the first method (the direct deflection) would fail. The higher the insulation resistance becomes, the more easily is this method applied, for it requires simply that the observations be taken at greater time intervals. Absorption of the charge causes no inconvenience beyond making it necessary that the wire be left charging during a longer time. In the second place it is far more accurate than either of the other methods; and, when there is added to these the extreme simplicity of the calculations, which are made without recourse to Napierian logarithms, it would seem as though the worth of the method were established.

University of Michigan.

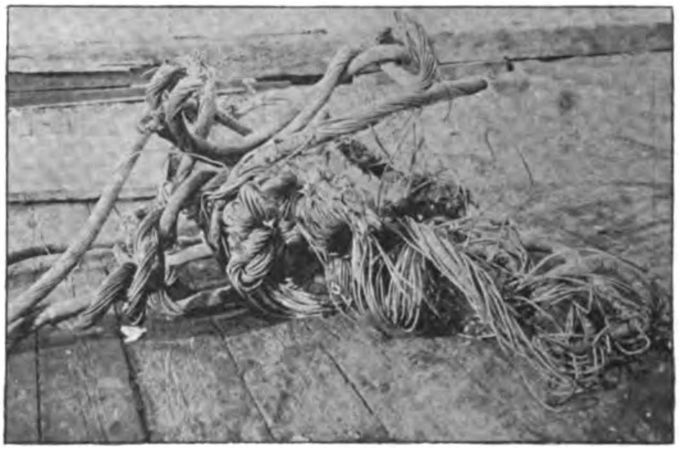
SUBMARINE CABLES IN SHALLOW WATERS—WHAT THEY HAVE TO PUT UP WITH.

BY

Herbert Laws Webb

SUBMARINE cables laid in shallow waters are often exposed to greater risks and rougher treatment than the great ocean cables which sometimes cost their owners a small fortune in repairs. Not long ago an ocean going steamship, in leaving her dock at Jersey City, ploughed up the soft bottom with her powerful propeller, and secured a costly and valuable catch in the shape of about a dozen submarine cables, which enmeshed themselves in the blades of the propeller so effectively that all the cables were torn asunder and the ship had to go into dry dock to clear her screw of the garlands of iron, hemp, and Kerite, with which it had become embellished—not to say embarrassed. The learned judge who presided over the argument as to whether the telegraph company, which owned the cables, or the steamship company, which owned the inquisitive vessel, was the aggrieved party, decided in favor of the latter, holding that a harbor is to be kept free for navigation, and that a steamer is entitled to plough through mud as well as water, cables or no cables. If the cables were thought to be secure because they were lodged in two feet of silt, why so much the worse for the cables, or rather for their owners. According to the learned judge, ocean steamers possess the right of way through the silt, even down to hard rock, and the waters of a harbor for purposes of navigation have no "bottom." This is cold comfort for owners of submarine cables in harbors, but by way of adding insult to injury the very practical suggestion was made that cables might be laid in a species of submarine trench, and thus be kept out of harm's way when ocean steamers (or others) find it necessary to "take the ground."

It is quite conceivable that the powerful machinery of an ocean steamer should make light work of gathering up, and rending into fragments, a dozen or so of submarine cables, but that a river tug should take to the same game and twist some hundred feet or so of heavily armored 7-conductor cable into a bunch of Gordian knots is a little too much. The accompanying illustration shows how effectively the tug did the work. The cable is the property of the American Telephone and Telegraph Company, and serves to connect the pole line across Staten Island with that running through New Jersey, the cable crossing the Kills between Linoleumville and Carteret. The tug caught up the cable in the most approved manner, according to the laws of harbor navigation, snatched it from its quiet resting place in the silt, and a stern battle between the pugnacious propeller and the inoffensive and defenceless, (though armored), cable ensued. Needless to say the propeller was victorious. The illustration, made from a photograph of the cable lying on the dock in New York, shows that beyond a doubt. The iron armor resisted vigorously, that also is plain; but it was never intended to withstand the attack of a river tug's propeller, so after a stout resistance, accompanied by endless writhings and contortions, it succumbed. The sea serpent itself could not have made a better fight. If the cable was vanquished, its enemy was also at least for a time placed *hors de combat*, for so closely were propeller and cable interlocked in their deadly feud, that the tug had to be brought to New York and put in dry dock in order to separate them. The snarl contains about one hundred feet of cable, and bears strong evidence as to good construction. Few would believe that a cable could resist long enough to be twisted up into such hideous shapes instead of breaking almost at once. The cable, which is a seven conductor, Kerite make, has been down for about five years and was found to be in perfect condition when repairs were made. Indeed the snarl testifies to that.



A SUBMARINE CABLE SNARL.

Not long ago Frank Stockton contributed to one of the magazines a nonsensical story, in which a startling incident was narrated. By a stroke of lightning a steamer had been converted into an immense magnet and had attracted to itself a submarine cable, which held it fast until the cable-ship came to the rescue. This flight of fancy is not altogether without excuse. There is a story of an ocean steamship catching up a piece of cable in the North river and towing it all the way from New York to Liverpool and back without discovering to what mysterious cause the strange reduction of speed on the round trip could be attributed. There is yet another story of a Sound boat which fouled a submarine cable in New York waters and towed a goodly length of it to New Haven. There the piece of cable was cleared away, coiled down on the dock, and subsequently sold by the steamboat company to another corporation whose business it is to maintain electrical communication between places near together and far apart. That corporation put the cable into service, and (so the story goes), is using it at the present time.

DUNKIRK, N. Y.—Judge Lambert has granted an injunction restraining the Board of Water Commissioners of Dunkirk, from buying machinery or materials for the construction of an incandescent light plant, and from raising by tax or otherwise money for creating or operating an incandescent light plant. The suit was brought in the name of A. J. Avery.

NEW STATION OF THE CLINTON GAS LIGHT COMPANY, CLINTON, MASS.

BY

A. C. Shaw.

As an example of another type of New England station of modern construction, I have selected that of the Clinton Gas Light Company, at Clinton, Mass., which possesses one most interesting feature, namely, that it was designed and built entirely to utilize the Evans friction system of driving. This is much more important than at first appears, as such a station, calculated for a certain amount of horse power and lamp capacity, would be absolutely inadequate in regard to space, were any other system of driving adopted.

About 5 years ago, the Schuyler Company of Middletown, erected a station of wood, and installed two arc machines, run by a Fitchburg high speed engine, which station was bought out by the Clinton Gas Light Company. About one year ago the Thomson-Houston alternating incandescent system was introduced, and as business continued to increase, it was determined to build a new station, and eventually land was bought adjacent to the railroad tracks, and in a convenient position for obtaining condensing water. The furnishing of plans and specifications for the complete construction of the station, and the necessary outside construction, was at once put into the hands of the Wright Electrical Engineering Company, of Boston, who afterwards took charge of the whole construction. It was early decided to adopt the Evans system of driving, and plans were drawn up to build the station to accommodate that system. As will be seen by an inspection of the ground plan, Fig. 1, the entire building is 135 ft. 6 in. long by 66 feet wide, and is one story high. The boiler room is 48 ft. 10 in. square, internal measurement, and has accomodation for five boilers. At present there are installed two Robinson boilers, built by the Robinson Boiler Works, of East Boston, Mass., who also furnished the iron smoke stack. The boilers are each of 125 horse power capacity, and work at a pressure of 90 lbs. per square inch. The roof is of wood 24 feet from the floor, and is supported by iron rod trusses.

The engine room is 45 feet 4 inches long by 47 feet 4 inches wide, and has accomodation for two 500 horse power double engines. At present there is installed one half of one of these engines, 250 horse power, of the Fitchburgh compound condensing type, built by the Fitchburg Steam Engine Company, of Fitchburg, Mass. The cylinder is 20 in. in diameter by 40 in. stroke, and the pulley fly wheel is 20 ft. 1½ in. in diameter by 43 in. face, weighing 30,000 pounds, and making 90 revolutions per minute, with automatic governor contained therein. The engine is belted to the shafting by a 42 in. belt, manufactured by Josiah Gates & Sons, of Lowell, Mass., having a drive of 40 feet. In addition to the large engine there is a small high speed Fitchburg engine of 75 horse power to be used when running night and also on day loads. The shafting and dynamo room, Figs. 2 and 4, is 38 feet long by 64 feet wide, and is calculated to contain two lines of shafting, though only one line is at present in place, the one shown in dotted lines being for increase. The shafting is of iron, $4\frac{1}{16}$ in. in diameter, and carries a 6 foot main driving pulley on quill shaft, three 75 in. pulleys with 15 in. face for driving the alternating machines, one 54 in. pulley with 10 in. face for the arc machines, and a 40 in. pulley with a 4 in. face for driving the exciters. Two Hill clutches are used for throwing in either engine. The engine and dynamo room roof is of wood with a strong iron truss, and has a slight pitch, and is covered with five-ply tar and gravel.

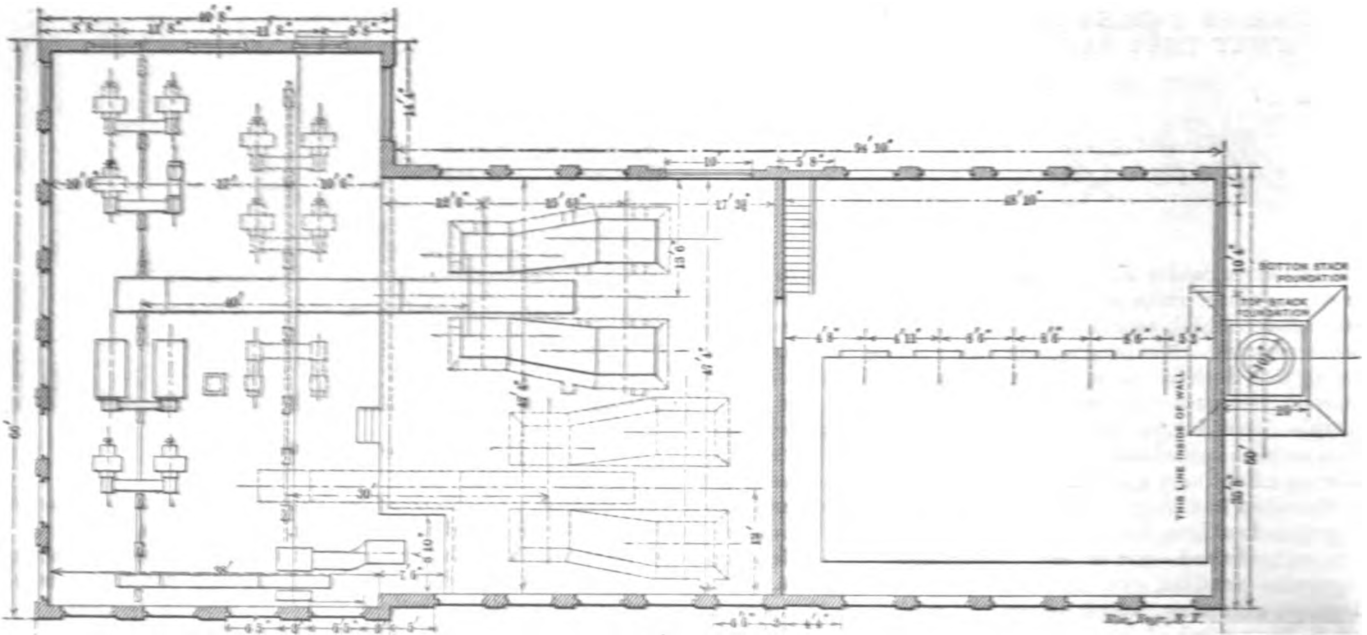


FIG. 1.—ELECTRIC LIGHT STATION AT CLINTON, MASS.—PLAN.
Plans and Specifications Furnished by the Wright Electrical Engineering Co., of Boston.

The foundations are built up of solid stone and brick, with granite cap stone. In the cellar is a Wainright heater, a Deane condenser, and feed water pump, and Korting injector. The engine flooring rests on brick piers, with 8x8 in. spruce stringers, and 3 in. spruce flooring with ⅞ in. maple flooring on top. The dynamo room floor is supported on brick piers, with 10½x14 in. Georgia pine stringers, 4x12 in. floor joists, and 3 in. floor plank with ⅞ in. maple on top for finish. The chimney stack is of iron, 90 feet high, 60 inches in diameter, and is calculated for 1,000 horse power. It rests on granite foundations 8 feet deep, the anchor bolts going to the bottom of the foundations, and is built to stand without guys and withstand any wind pressure.

At present there are in service two Schuyler 45 light, 1,200 candle power arc dynamos, two 650 light Thomson-Houston alternating dynamos, two exciters each capable of exciting both alternating machines, and a 30 horse-power Thomson-Houston motor generator.

The wiring from the dynamos to the switchboard is all underneath the floor, and is strung on porcelain knobs, Okonite wire furnished by the Pettingell-Andrews Company, of Boston, being used throughout. One of the special features of the station is the switch-board, a view of which is given in Fig. 3, and which was designed and built by the Wright Electrical Engineering Company. It is composed entirely of iron and slate, and all the necessary instruments for controlling the dynamos are mounted most conveniently upon it. The switches are so arranged both for the arc and alternating machines that any machine can be thrown upon any circuit, or one machine can be thrown upon all the circuits. The exciter switches are so arranged that each alternating machine is ordinarily run from its own exciter, but, in case of failure of one exciter, by throwing the switch both alternating machines can be run from either exciter. The workmanship on the switchboard is excellent, and the arrangement of the necessary resistance boxes, ammeters, voltmeters, switches, etc., is unique. The whole board being composed of iron and slate is, of course, absolutely fire proof. A few feet away is a special small switch-board for the Bernstein series incandescent system, of which there are two circuits of 44 lamps each of 25 candle-power. These lamps are run from the alternating machines, the system being known as the Thomson-Houston street incandescent.

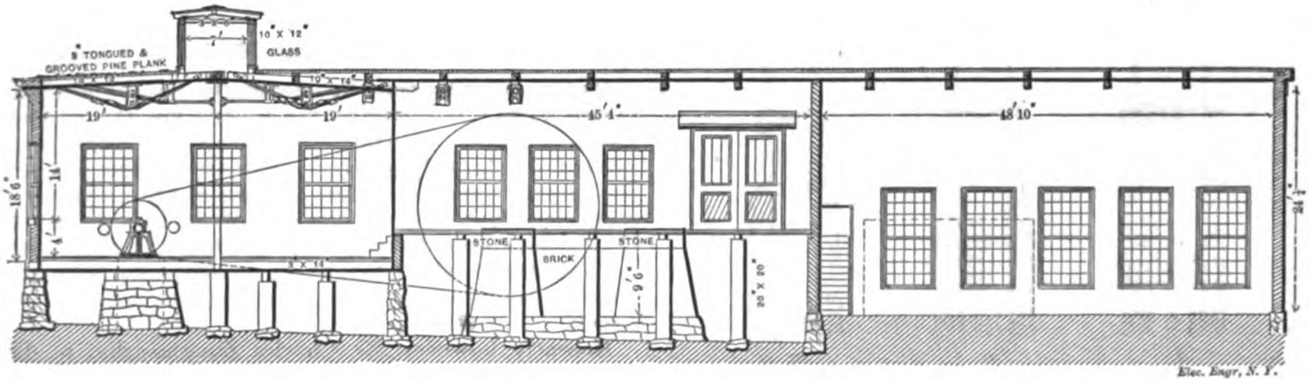

FIG. 2.—ELECTRIC LIGHT STATION AT CLINTON, MASS.—SECTIONAL ELEVATION.
Plans and Specifications Furnished by the Wright Electrical Engineering Co., of Boston.

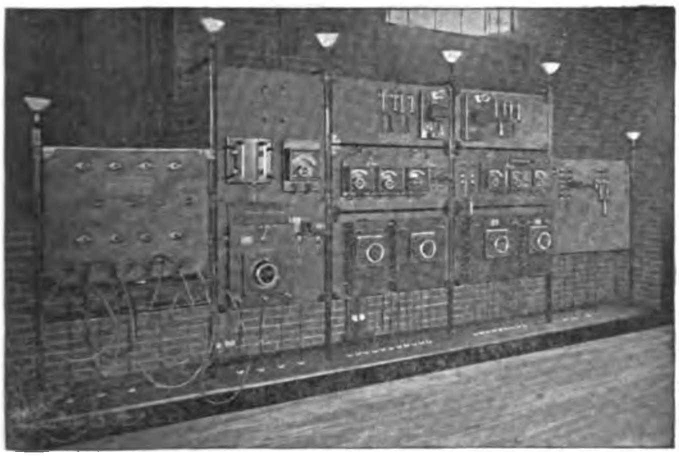

FIG. 3.—SWITCHBOARD—ELECTRIC LIGHT STATION AT CLINTON, MASS.

Directly over the main switchboard is the wire tower, which is reached by a permanent ladder, and in which are contained the lightning arresters, the wire from the switchboard to the outside connections being all Okonite.

About 600 poles have been erected on the outside construction work, and about 35 miles of wire furnished by the American Circular Loom Company of Boston. There are at present in service in Clinton 50 arc lamps, 135 series incandescent 25 candle-power lamps for street service and 650 16 candle-power incandescent lamps for store, factory, and house service, one factory alone using about 200 lamps.

The present officers of the company are: Mr. Eli Forbes, president; Mr. Henry N. Bigelow, treasurer and general manager, and Mr. Wm. H. Spaulding, superintendent, to whom with Mr. Charles H. Herrick of the Wright Company, my thanks are due for the foregoing particulars. The following gentlemen are the directors of the company: Messrs. Eli Forbes, John E. Thayer, Herbert Parker, John R. Foster, Henry W. Bigelow. The plant is a model one all through, and the whole work, both inside and outside reflects great credit on the Wright Engineering Company, who furnished not only the plans and specifications, but superintended the construction throughout. Much of the success of the station is without doubt due to the energy and intelligent management of Mr. Bigelow and Mr. Spaulding.

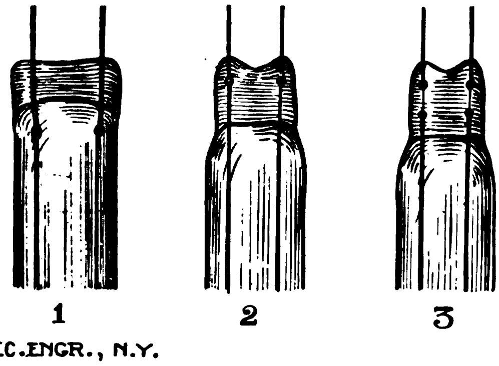
THE WADDELL SIGNAL SYSTEM.

This system, which is now being exhibited at No. 86 World Building, this city, is intended to prevent railroad accidents in tunnels and elsewhere. For this purpose each locomotive carries a battery or small magneto, driven by an engine, and a bell. Between the rails are laid a pair of conductors which are divided into sections, and upon which bear contact wheels or brushes connected with the battery and bell on each locomotive. With only one locomotive on a section the circuit to the bell is broken, but the instant a second locomotive enters upon a section the conductor circuit between the tracks is closed and the bell in the cab sounds an alarm. Should a third or fouth train enter upon a section, upon which two trains were already signaling, they would also receive the signals independent of their position. The arrangement is such, also, that an accident to either the receiving or generating apparatus on any engine would not interfere with the reception of signals by other engines upon its approach. By means of proper connections, bells placed at crossings can be arranged to ring when a train arrives within a given distance and gates could be automatically operated in the same way.

The system is now being exploited by Mr. Maurice Maas and is illustrated by working models at the place mentioned above.

REDUCTION OF PLATINUM IN THE EDISON INCANDESCENT LAMP.

The increasing scarcity of platinum, with its corresponding increase in price, has forced lamp manufacturers to exercise the greatest economy in the use of this valuable metal, while on the other hand, not a few attempts have been made to find a substitute for it. The great value of platinum as a seal, in connection with glass, is due to the fact that it has practically the same coefficient of expansion as glass itself; and again, its nature is such that glass adheres to it firmly. In order to show in what manner the reduction in the amount of platinum required in lamps has been carried out, we give in the accompanying illustrations three views of the successive steps in this direction which the Edison lamp has undergone since its early manufacture. Thus, in Fig. 1, is shown a stem in which two pieces of platinum are employed, the ends of which extend some distance both inside and outside the sealed portion. On account of the low conductivity of, and the heat produced in, the platinum wire, the latter was required to be comparatively large.



Figs. 1, 2 and 3.—Platinum Lamp Terminals.

To reduce this as much as possible, the method shown in Fig. 2 was next extensively employed. This consisted in first soldering a platinum wire of smaller cross section to a copper wire and sealing in such a manner that the platinum wires extended but a short distance into the seal. By this method considerable platinum was saved over the original form adopted.

The latest method, however, has brought down the amount of platinum required to a far smaller quantity than even the one described, and the manner in which this has been accomplished will be readily seen in Fig. 3. Here, it will be noticed, a short piece of platinum wire is joined to two copper wires, one of which passes into the lamp bulb and the other out to the socket terminal. The glass is sealed around this platinum wire and for a short distance beyond, covering a small portion of the copper wire. This forms a perfect seal, and, at the same time, reduces not only the length of platinum wire required to an 1-8 of an inch, but, in consequence thereof, also allows of considerable reduction in its cross section.

A SUGGESTION IN ARC LIGHTING.[1]

BY PROF. C. HANFORD HENDERSON.

The speaker called attention to the fact that progress in illumination has consisted in the substitution of continuous for reservoir systems. In arc lighting the supply of energy is continuous, but the light-yielding substance, carbon, must be frequently replenished. The question as to whether arc lighting could be made continuous had therefore presented itself, and an experimental test was made to use gas issuing from hollow wrought-iron terminals, in place of the solid carbon. It was found that the gas and the arc formed two mutually repellent crescents of light; the terminals were fused and one of the gas jets was closed up. This negative result not being thought conclusive, the suggestion was brought before the Section in the hope of discussing the question as to whether the problem was sufficiently promising to merit further attention.

Prof. Houston stated in discussion that hollow carbon electrodes had been used at different times since 1852, fed by hydrocarbon oil, and by gas containing pulverized carbon, and the like, but without success, owing to the fusion of the terminals. As the intensity of the light varies with the sixth power of the temperature, he considered a continuous arc impossible with our present refractory materials.

ZIPERNOWSKY'S ELECTRIC HEATER.

Heretofore heating by electricity has been obtained in two ways; the first by the electric arc, the second by means of a body introduced into an electric circuit, which presents a relatively greater resistance to the passage of the current transmitted than the rest of the circuit within which it is included. In the case of the electric arc there is total separation between the electrodes. In the second method there is absolute contact or continuity between the body presenting high resistance and the balance of the circuit.

Recently, however, Mr. Charles Zipernowsky, of Buda-Pesth, Austria, has devised a method which may be said to stand midway between the two mentioned, and which consists in the employment of an imperfect contact, its degree regulating the intensity of the heat.

The accompanying illustrations, Figs. 1 and 2, show a view of the apparatus in perspective and in vertical section.

As will be seen, the metal tube A is provided with perforations and a solid soldering point B. The soldering portion and handle are connected to one of the leading-in wires by means of a connector H. Within the tube A is another tube I, having a contact J attached to its outer end, and near to the soldering point. Near the right hand end of this tube is a collar K, over which, and around the tube is placed a helical spring L, bearing at one end upon the collar, and at the other upon the insulating cap M secured to the tube A. By rotating this cap the degree of contact between the point J and the soldering end B may be regulated.

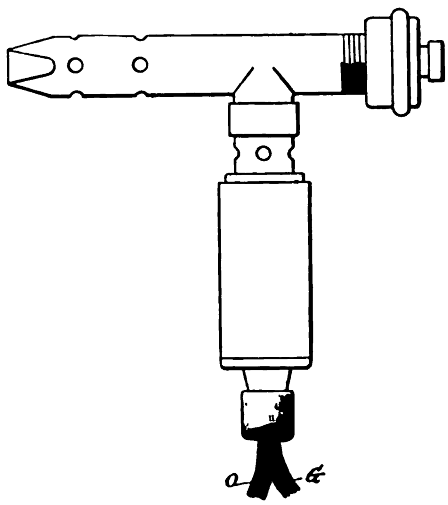


Fig. 1.—The Zipernowsky Electric Heater.

As previously stated, the heat obtained is due entirely to the resistance of the imperfect contact. It will readily be understood that where the tubes of conducting material and the point J are forced into contact with the part B no heat will result when the quantity of current transmitted is within the conducting capacity of the point; and, further, that if the point be brought into imperfect contact without increasing the quantity of current transmitted, considerable heat will be evolved, its intensity depending upon the resistance at the contact points.

---

[1] Abstract of a communication to the Electrical Section of the Franklin Institute.

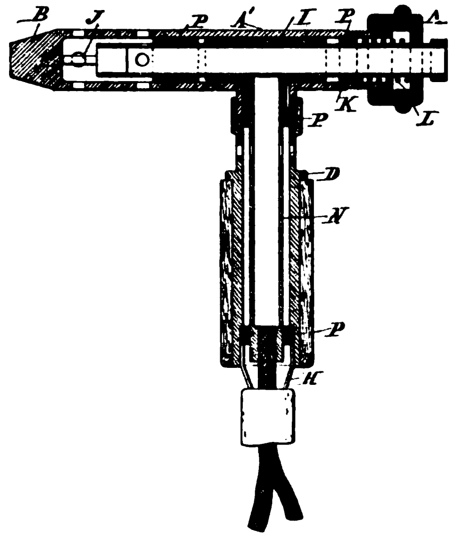

FIG. 2.—THE ZIPERNOWSKY ELECTRIC HEATER.

The perforations are simply for the purpose of keeping the tubes cool, by allowing the heated air within to escape.

NALDER'S HIGH RESISTANCE GALVANOMETER.

THE galvanometer illustrated in the accompanying engravings is designed so as to have the maximum insulation, in order that it may be wound to the highest possible resistance. The instrument, in fact, is wound to as high a resistance as 350,000 ohms with copper, requiring about 18 miles of wire. The coil boxes, which are hinged, are kept closed in position by means of a spring button, thus rendering the use of a screw-driver unnecessary; to open these the button has only to be turned. The suspension is raised by means of a nut; this action does not in any way twist the fibre, the torsion in which is removed by means of the lower milled head which turns independently of the threaded pin. The whole system of the suspension can be removed bodily by loosening the milled side nuts. In order to avert as far as possible, the action of light upon the ebonite, the glass, front and back, windows of the case are provided with black silk blinds.

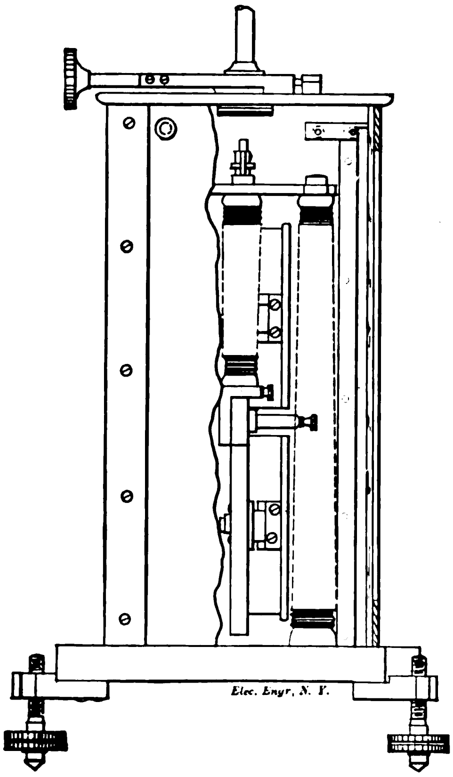

FIG. 2.—NALDER'S HIGH RESISTANCE REFLECTING GALVANOMETER.

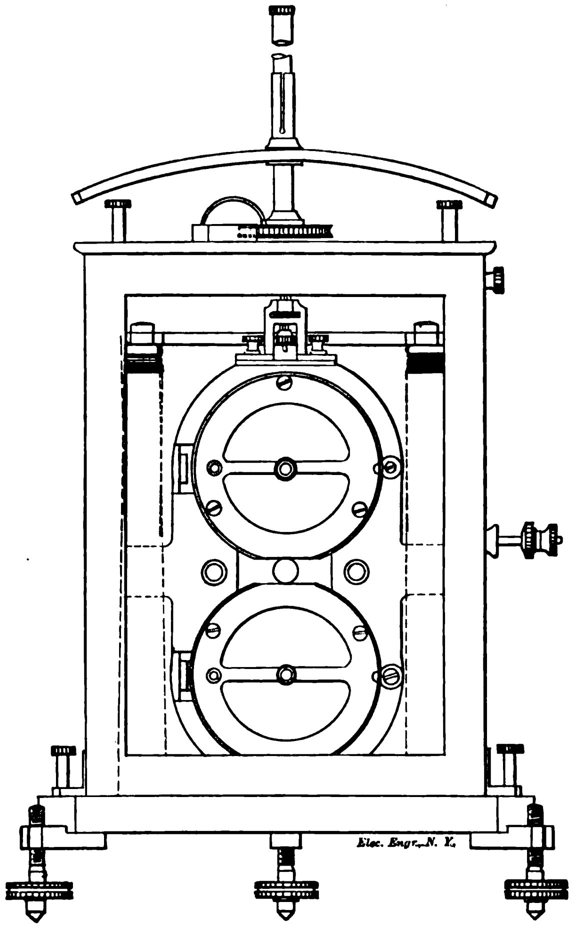

FIG. 1.—NALDER'S HIGH RESISTANCE REFLECTING GALVANOMETER.

This instrument was first made for the Central Institution of the City and Guilds of London. Mr. Mather ofthat institution designed the plan of the pillar supports, and the coils. The instrument is made by Nalder Bros. & Co., of Clerkenwell, London.

MR. MAVER'S NEW BOOK ON TELEGRAPHY.

Mr. William Maver, Jr.'s new book on American Telegraphy, upon which he has spent several years in preparing the subject matter, is now passing through the press. The book will comprise about 600 pages, including over 400 diagrams and engravings. In this work the systems of telegraphy now in use in America, their apparatus, method of operation and the electrical laws involved therein are exhaustively treated; clearly, exactly, and fully described by the aid of very complete and original diagrams, and everything brought up to the present time, 1891.

It is believed that this work will contain more complete information than has ever before been published; in fact the details of many of the systems herein fully explained and thoroughly illustrated, have never before appeared in print.

The book is being published by Messrs. J. H. Bunnell & Co., 76 Cortlandt St., New York, who hope soon to announce its readiness for sale at a moderate price. The well-known ability of Mr. Maver, and his long experience in the telegraphic field, ensure a very large sale for this work.

ELECTRIC VERSUS STEAM ROADS.

THE beneficial results accomplished in St. Paul by the adoption of electric traction were commented upon in these columns two weeks ago. Our text was an editorial article from the St. Paul *Pioneer-Press*, which said that the introduction of electricity had been worth ten real estate booms to the city. We now have before us another remarkable expression of sentiment, from the sister city of Minneapolis. The *Tribune* of that city announces that the steam roads between the two places have made up their minds to withdraw from competition with the electric line, which, though still so recent, has cut into their business to such an extent that nothing is left of it. These steam roads have been in possession of the field for 20 years, and have been of much benefit to the two communities. Their fares, however, have been 30 cents for the single trip of 10 miles and 50 cents for the 20-mile round trip. When the Lowry electric interurban line went into operation last Fall its fare was put on a 10 cent basis, or 20 cents for the round trip. Besides this, transfers are given at each end of the line to the connecting street car lines, so that the fare comes down in the vast majority of cases to 7½ cents for single trip, or 15 cents for the round trip, whereas the street car fares have to be added in the case of a steam trip, making the round fare 60 cents. Thus it figures out that the electric cars have knocked 45 cents off the average cost of a round trip, making it only one-third of what it was before under the old steam régime.

Such facts as these support us fully, we think, in our assertion made last week and on other occasions that in a few years all the "commuter" traffic around our great cities would be handled by electricity; and they also point significantly to the easy accomplishment of greater work beyond. It is noteworthy that the electric cars of the St. Paul–Minneapolis line have thus made their fight and won it, and put themselves on a paying basis, with inadequate facilities, and with all the drawbacks unavoidably incidental to a new traction service. In view of what has already been accomplished, President Lowry is substituting for the 30 h. p. motors others of 50 h. p. which will also haul trailers; and, if necessary, trains will be started from each city every minute, beside making greater speed.

This is the record of but two cities, but there are many others that can tell of like development through electricity, and it seems incredible that such a community as Brooklyn, with its great distances, should hesitate to avail itself of similar advantages. We doubt, however, whether the score or two of malcontents who have put themselves forward, can fairly claim to voice the intelligent sentiment of a community which is generally in no wise wanting in public spirit, civic pride, and an appreciation of science and art as applied to the welfare of the people.

TUNNEL LIGHTING AND VENTILATION.

THE bill of Senator Ahearn, which Governor Hill has approved, confers upon the New York State Board of Railroad Commissioners authority to compel the lighting and ventilation of all tunnels within the State, which are used by steam railroads. The Commissioners already had power in this direction, but the bill gives added weight to their recommendations, places a limit upon the time within which they must be complied with, and imposes severe penalities for any refusal or neglect to carry out the Board's suggestions. As our readers are aware, the Board has been looking into the matter of lighting, and has taken evidence on the subject. Some of that "evidence," directed against the electric light, has been of a very amusing nature, and it would appear that more than one intelligent man has still to discover the difference between arcs and incandescents. Pending action of the State Board, it is interesting to note that Mr. Paul H. Brangs, the electrical engineer of the Delaware, Lackawanna and Western Railroad, with other officials of that line, has lately been inspecting the plant in the Hoosac tunnel, with the view of adopting similar means, if satisfactory, for the Hoboken tunnel. The redeeming feature of the Hoosac tunnel, which is 5 miles long, is its method of lighting by incandescent lights, run on the alternating system and placed 40 feet apart. These allow work to be done with ease and facilitate the running of the trains, as the only other lights or signals of any kind are green ones used to designate the distance from the portals. Since the introduction of these lights no lives have been lost, whereas, formerly, brakemen and trackmen were often killed. The cost of the system is slight, being only about $30 per day of 24 hours, which includes all expense. The power is derived from two boilers and a [illegible] h. p. Corliss engine which runs three large dynamos constantly. There are 1,200 lamps of 16 c. p. in two rows, one on each side of the tunnel. It is said that under normal conditions the locomotive engineer can see the track nearly a mile ahead, and is in no way dazzled by the little incandescents. We trust Mr. Brangs may soon have the chance to be a pioneer in this work in this part of the country.

THE FRANKFORT ELECTRICAL EXHIBITION.

THIS week sees the beginning of the Frankfort Electrical Exhibition, the date of opening having been fixed for May 16; and while there was still much to be done, the show has at least made a start. It will probably not be in full running order for another month, and as it lasts until Fall, Americans who intend to visit it have plenty of time before them. There is every reason to believe that the exhibition will be a success, and that each of the twelve classes will be well filled. One of the most important pieces of work in connection with the exhibition is the long distance transmission of power from Lauffen to Frankfort, of which we have already given very full details. The experiments of Prof. Hertz will also be repeated and amplified. Special attention will also be paid to electric railroading, electric boating, and electric mining.

It is quite possible that the exhibition may furnish some suggestions for the electric exhibit at the Chicago World's Fair, which has seemed so far from being carried out on right lines that Mr. Edison has himself made the matter one of personal attention during a visit to Chicago. Prof. Barrett and Mr. Sargent both mean well, and have excellent ideas, but under existing arrangements they appear to have little opportunity to collaborate. But matters will soon straighten out, we hope, and promise better than they now do.

ELECTRIC HEATING.

IN tracing the history of an art, it is frequently instructive to compare it with other parallel arts, and to show in what manner the developments of the one follow closely upon those of the other. It was but a comparatively short time after the recognition of the method of producing light from electricity on a commercial scale that the availability of the same source of energy for heating purposes, both special and general, was recognized. Naturally the arc as a source of heat attracted most prominence, and not a few electric furnaces were constructed on this principle. Next came the employment of resistances heated up by the passage of the current and employed in a variety of ways for the heating of cars and many kinds of special apparatus. In this issue we draw attention to the third method, which may be said to present a close anology to what are termed semi-incandescent lamps of the Werderman type. In this method of heating, devised by Mr. Zipernowsky, heat is produced by the resistance caused by bad contact, the materials of which the contacts are formed being such as to withstand the action of the heat generated. It is evident that this method would not of itself give rise to an increased efficiency over a form in which wire resistances are employed, but it may under certain circumstances permit of the production of a higher degree of heat with a compact arrangement of parts.

PLATINUM LEADING-IN WIRES.

SOME time ago in referring to the improvements in lamp manufacture which had made it possible to reduce the price of incandescent lamps over 66 per cent. within a comparatively short space of time, we drew attention to the increasing cost of platinum and its effect upon the cost of manufacture of such lamps. The most natural remedy for the reduction of this item of expense would be the substitution of some other material for it; but as some one has naïvely remarked, the substitute for platinum which has all its characteristics and is able to withstand the tests of platinum, *is* platinum. A substitute being, therefore, still a thing of the future, the only way out was to reduce the quantity of platinum required for the leading-in wires. What can be accomplished in this way is well shown in the progressive stages of incandescent lamp manufacture exhibited on another page. Whereas formerly but a few hundred lamps required an ounce of platinum wire, at present as many thousands can be effectually sealed by the use of the same weight of material. It may, perhaps, be due to such economies as these that the price of platinum has lately fallen from its very high figure of the past year or two.

Standard Cells.

THE working electrician naturally feels ill at ease when in doubt as to the accuracy of indication of his working instruments, and hence desires to have at hand some convenient standard by which to test their accuracy. The standard cell is one of the most convenient and handy of such reference standards, and any improvement which can increase or ensure its accuracy, as well as permanence, is therefore worthy of special consideration. Our readers will therefore be interested in the modification introduced by Mr. Carl Hering, which we describe in another column, and in which he overcomes some of the difficulties heretofore encountered by constantly renewing the surface of contact between the two solutions employed, and thus preventing their mixture. While voltaic cells of various construction still remain the most reliable of working standards, their use is nevertheless accompanied by not a few inconveniences. A standard of E. M. F. which shall be simple in construction and permanent in its indications under all conditions, will therefore be a great step in advance, and will, we believe, be soon forthcoming.

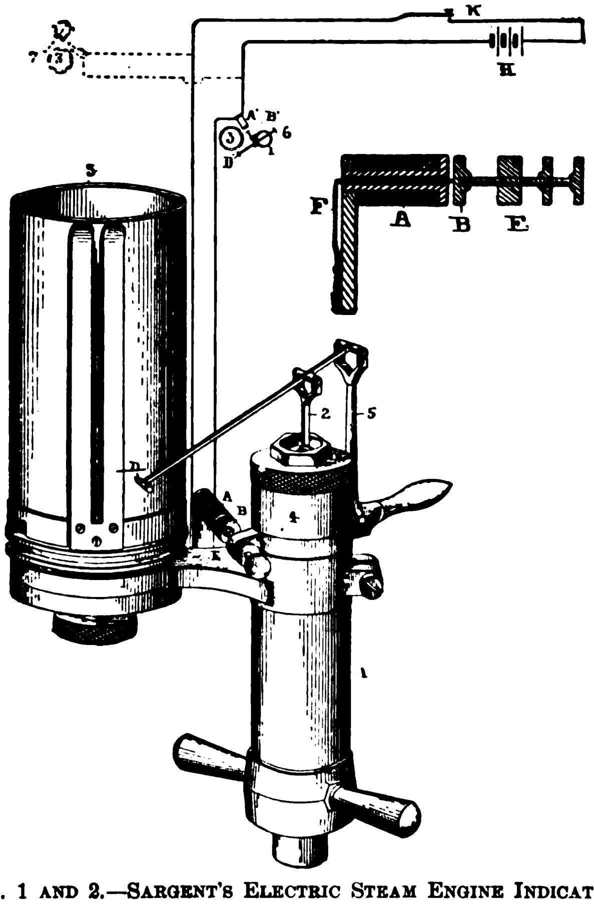
The New York Subways.

THE New York Board of Electrical Control has had the term of its existence lengthened, and has now taken an important step in dividing up the work done under its supervision. The old Consolidated Subway Co. is to restrict itself to high tension conduit building, while the new Empire City Subway Co. is to do all the low tension work, including telegraph, telephone and incandescent lighting. In other words, the new company becomes a dominant, controlling factor. Why it should have been necessary thus to split up the work we cannot quite see, but an explanation could probably be obtained from Tammany Hall if it chose to give one.

SARGENT'S ELECTRIC STEAM ENGINE INDICATOR.

In the case of a triple expansion engine with indicators placed on the ends of each cylinder it is desirable, in order to obtain accuracy, to indicate the several cylinders at exactly the same instant. Heretofore it has been practically impossible to operate the several indicators employed, at exactly the same moment, and for the same period of time, as each indicator was separately controlled. With these facts in mind, Mr. Frederick Sargent, the well-known electrical engineer of Chicago, has provided a means whereby the recording devices of several indicators can be operated from a distance at the same instant by one person, and the time of contact at each indicator be made of exactly the same duration.

The manner in which this has been accomplished is shown in the accompanying illustrations, Fig. 1 being a perspective view of the indicator, and Fig. 2 a sectional view of the operating magnet. As will be readily understood, A is an electro-magnet in circuit with a battery, and the key K. The armature, B, is fixed upon the movable sleeve of the indicator cylinder, by turning which the pencil is brought into contact with the paper on the drum. The armature is normally held away from the end of the magnet, and hence, also, the pencil from the drum, by means of the spring F, Fig. 2. When the circuit is closed, however, the sleeve is drawn around, the pencil is pressed against the paper on the drum, and the card taken.



Figs. 1 and 2.—Sargent's Electric Steam Engine Indicator.

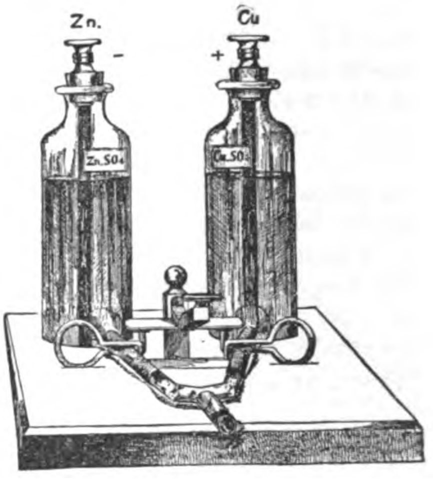
It is evident that a number of these magnets may be placed on the same circuit as shown in Fig. 1, and that by this means the indicators will all be operated at exactly the same instant, by merely closing a single key.

Mr. William Morehead, who has been connected with the electric light company at Ogden, Utah, for some time past, has accepted the position of electric light inspector at Salt Lake.

A NEW FORM OF STANDARD CELL.[1]

BY CARL HERING.

In a number of forms of battery cell in which two bottles or reservoirs are connected together by a tube, the mixing takes place quite rapidly, unless the pressure of the liquid is exactly the same in both bottles, a condition not always easily complied with. Some time ago the writer had occasion to use a cell of this form devised by Prof. Barker, which consisted of two bottles containing the two liquids with their respective electrodes, the bottles being connected at their bottoms by a small tube with a stopcock. This cock was opened only during the moment when the cell was being used. But even during a few seconds no small amount of mixing took place, especially if the pressure was different in the two bottles. It is very difficult to avoid this difference of pressure, owing to the different specific gravities of the liquids, and their different heights in the two bottles. The writer therefore modified this form by inserting two stopcocks in this tube and allowing the portion of the tube between the two cocks to communicate directly with the air, as shown in the accompanying engraving. Thus the liquids, which mix at their point of contact, are allowed to drain off as rapidly as they mix. As there is an outward flow of the liquids through the cocks, the mixed liquids cannot pass back into the bottles. The liquids in contact with the electrodes will therefore always remain pure. To prevent too rapid a flow, which would needlessly waste the liquids, some filter paper, cotton or asbestos is packed into the tubes. The intermediate tube may be drained completely, as there is always a film of liquid sufficient to answer for a contact if the cell is used on open circuit, which is the only way any standard cell should be used. It was even found that the film of liquid through the cocks when closed, was sufficient to give an electro-motive force, which, however, falls as soon as the slightest current is allowed to flow. The internal resistance of such a cell is naturally quite high, from 10,000 to 20,000 ohms, but this is no disadvantage for the usual class of open circuit testing.



Hering's Standard Cell.

Such a cell may be kept standing indefinitely, and is always ready for use. A quantity of zinc scrap should be kept in the bottle containing the zinc solution, and copper scrap in the other, both out of contact with the electrodes, for the purpose of freeing the liquids of impurities, should any mixing occur.

In experimenting with this cell, it was found that the slightest pressure upon the corks produced decided differences of potential in the E. M. F. of the cell. It was, therefore, found necessary to use corks with holes through them to prevent pressure from being exerted upon the surface of the liquid.

CREAGHEAD ENGINEERING CO.

The Creaghead Engineering Co., of 99 West Fourth street, Cincinnati, O., was incorporated in Covington, Ky., some weeks ago. At present they do not expect to do any manufacturing business, but are simply acting as agents for manufacturers, dealing in electrical supplies of all kinds, in addition to which they act as consulting and contracting engineers for all kinds of electrical plants. They are also the accredited representatives of the Westinghouse systems there. It is within the range of possibilities that they may begin the manufacture of electrical specialties in the near future. The officers of the company are: H. D. Emerson, president; Thos. J. Creaghead, vice-president, and C. L. McCrea, treasurer.

CENTRAL STATION MANAGEMENT AND FINANCE.—V.

BY

Horatio A. Foster

Electrical Department.

From all the reports mentioned last week, the Dynamo Engineer gathers data for his own which is somewhat contracted, and does not of necessity contain much of any of them. No. 6 and 6A are two sizes of this, and contain place for mention of names, time of employees, and the times of the different runs, as well as time of starting and stopping dynamos, this last being taken from the arc switchboard list, and report of dynamo tender as to the running of the other machines. In this again, as in the Chief Engineer's report, the storeroom is depended on for a statement of supplies used.

BLANK NO. 6.—DYNAMO ENGINEER'S REPORT.

Superintendent's Report.

From the department reports the superintendent makes his report on blank No. 9. This is a general résumé of the reports of chief engineer and dynamo engineer, together with reports of new contracts and such data taken from the office. It serves to state as briefly as possible the general condition of the station departments to the officials in authority. It serves also to record any changes or other matter which it is well to note for future reference.

Storeroom.

The supply department in stations large enough to afford it should have a good storekeeper, one who can keep clean records and make out his reports accurately and on time. In smaller places this department is easily attended to by the office clerk, and in his absence on collections or other duties the key can be turned over to some member of the day force around the station. As all orders for supplies must be accompanied by the proper requisition from foreman (blank No. 10) all material is easily accounted for. It is very important that the foremen or department head should sign all supply orders for construction material as it many times saves dispute.

BLANK NO. 6A.—DYNAMO ENGINEER'S REPORT.

In the case of the general operating supplies, such as carbons, waste, oil, etc., a supply order is written and signed by the man who gets the material, and it must show the proper order number of the department for which it is intended. Figures of coal and water supply are taken from the engineer's daily report.

The storekeeper's records are a receiving book in which are entered all supplies received, stating date received, whom from, items and any unusual particulars. This book comes in very handily in checking up bills, and is also very convenient for future reference. A delivery book is needed also on which are entered all supplies drawn out on requisition of the foremen and operating departments, it being made up from the requisition tickets, and in case of a large breakage of incandescent lamps, it is very convenient to keep a register of such lamps, giving the name of the customer and having a number of columns, say, one for each month, thus showing at what point in a circuit the lamp breakage may be excessive, and at the same time, the part of the year when it is the heaviest. Such a record also gives a good basis on which to calculate the average life of lamps. Each incandescent lamp taken from the storeroom should be accounted for by the return of either an unbroken lamp or its base.

CHLORINE IN HYDROCHLORIC BICHROMATE BATTERIES.

BY

Chas. J. Reed

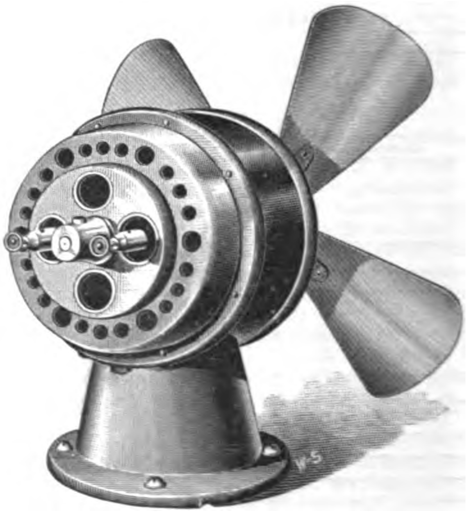
IN THE ELECTRICAL ENGINEER of May 13th, Mr. Steinmetz points out that he was unable to find free chlorine in the bichromate cell in which hydrochloric acid is present, and states that the reduction of chromic acid by hydrochloric does not take place in the cold.

Some years ago the writer had occasion to investigate this subject, and found that the reduction *does* take place at all temperatures above the freezing point. The action is not very rapid at low temperatures, especially with dilute solutions, such as were probably used by Mr. Steinmetz. When the concentrated solutions, cooled to 0° C., are mixed one drop at a time in a thin layer on the bottom of a flat evaporating dish surrounded by melting ice, sufficient chlorine is evolved to almost instantly discharge the color of litmus and other organic coloring matters. Very dilute solutions will do the same if sufficient time is allowed.

I am glad to learn that in the battery solution, this evolution of chlorine is not fast enough to be objectionable. It would be still more interesting, however, to know whether tools and instruments would not be seriously corroded by standing two or three months in the same room with an open battery of this kind.

THE NEW MESTON ALTERNATING CURRENT FAN MOTOR.

THE question of designing an economical and efficient motor for operation from a source of alternating current is one which has recently received a vast amount of attention, and many forms, more or less complicated, have been brought out. For fan work, it is especially desirable to be enabled to use a motor operated by an alternating current, and it is just as desirable that the motor should be efficient and of light weight in proportion to the power developed for running fans as for any other heavier work. The new motor, shown in the accompanying illustration, is manufactured by The Emerson Electric Mfg. Company, of St. Louis, Mo. It fulfills all the above-mentioned requirements in the highest degree. It is, of course, self-starting, always running in the pre-determined direction and never exhibiting the persistent disposition to stand still, which has been noticeable in some of the alternating motors proposed and which required to be started by hand. It runs at 2,500 revolutions, absorbing 1.8 amp. on 52 volt circuit. It is extremely simply constructed and develops $\frac{1}{8}$ h. p. and will operate equally well either on direct current incandescent, arc or alternating circuits. The mechanical workmanship is of the best, and the whole machine is most compact, neat and reliable.



THE MESTON ALTERNATING MOTOR.

THE NEW WESTERN UNION HEADQUARTERS AT ST. LOUIS.

BY

RJ Hewett

SOME sixteen months ago the main office of the Western Union Telegraph Co. was destroyed by fire. Since that time the company have occupied temporary quarters at 215 Pine street. Last fall the Lucas building, on the south side of Pine street, between Fourth and Broadway, was selected for permanent quarters and the work of alteration and fitting up was inaugurated and pushed forward with vigor. On Monday, May 11th, the building was finished and occupied by the several departments. The receiving department, manager's office and book-keepers, occupy the first floor. The second floor is occupied by the division superintendent, Mr. L. C. Baker, and the several departments pertaining to his division. The third floor is occupied by the Gold and Stock Telegraph, cloak rooms, lunch counter, lavatories, lamp room and also as a distribution room for the instrument cables of the operating room. The fourth floor is occupied by the operating department.

The power plant is located in the basement of the building, which is 135 feet long by 36 feet wide and 11 feet high. The basement is divided into three divisions, the front being for the linemen, the middle portion is occupied by the engine and dynamo plant, and the rear portion by the boilers. The basement is floored with granitoid throughout. Steam is supplied by two plain tubular boilers, each 16 feet in length with 66 inch shells, capable of carrying 100 pounds pressure. They are fitted with high and low water alarms and damper regulators. Two Deane duplex steam pumps supply feed water.

The engine and dynamo room is 36 by 47 feet, and as it contains the most interesting electrical feature about the building it will be described more fully. A Rice automatic engine of 85 h. p. capacity drives a 400 light U. S. dynamo which supplies lights throughout the building. Three Rice automatic engines, each of 15 h. p., drive three gangs of telegraph dynamos. One upright engine drives two Root blowers for operating the pneumatic tubes. There is also an elevator engine and a small 5 h. p. upright engine for driving ventilating fans. All engine cylinders are lubricated from a large oil tank in the boiler room, the oil being forced into the main supply pipe by steam pressure. All steam pipes are covered with the Flegel air space covering.

Each 15 h. p. engine is belted to a separate line shaft to which is belted a gang of 5 or 7 telegraph dynamos. The line shafting is supported entirely independent of the building by means of an iron framework supported on iron pillars anchored into concrete foundations, the pillars being connected together at the top by I beams and the shafting hung to heavy wood cleats attached to channel beams. This arrangement prevents noise or vibration being communicated to the building, besides adding to the general stability of the gearing. The shafting pulleys and pulley hubs are all highly finished. The pulleys which drive the local circuit and loop circuit dynamos are provided with friction clutches supplied by the Fall River Manufacturing Co., all other pulleys being fixed rigidly to the shaft.

Each gang of dynamos is mounted on a heavy wooden bed-plate which is bolted to a concrete foundation, the top of the bed-plate being 20 inches above the floor.

Nineteen telegraph dynamos, supplied by the C. & C. Electric Motor Co., are arranged in three gangs, two gangs of seven and one gang of five. The two gangs of seven are each arranged into sections for supplying main line circuits, local circuits and loop circuits. Five dynamos of each gang are connected in series and supply the main lines, the sixth dynamo supplies the loop circuits, and the seventh supplies the local circuits. Two main circuit sections supply positive and negative current to main lines, one section having its positive pole connected permanently to earth and its negative pole to the switchboard, while the other section is arranged in a reverse manner: that is, its negative pole is connected to earth and its positive pole to the switchboard.

One set of loop and local circuit dynamos have ample capacity for supplying all circuits, the other set being held in reserve.

The third gang of five dynamos is a reserve main line set, all five being connected in series. The series dynamos are wound for a potential of 80 volts, at a speed of 1,250 revolutions, but ordinarily will be run at 70 volts. A set will, therefore, give the following potentials: 70, 140, 210, 280 and 350 volts. The loop dynamos are wound for 30 volts at a speed of 1,250 revolutions, but will be run at 25 volts. The local circuit dynamos are wound for 10 volts at a speed of 1,250 revolutions and will be run at six volts. The current capacity of the dynamos is as follows: Main line dynamos, 20 amperes; loop dynamos, 50 amperes, and local dynamos, 150 amperes.

The fields of the series dynamos of each set are excited by the fifth potential dynamo, each field having a regulating resistance box in circuit with it giving independent regulation for each dynamo. Regulation can also be effected by changing the potential of the fifth dynamo. The reserve gang of five dynamos is arranged so as to supply positive or negative current to line as the emergency may require. This is done by simply reversing the connections of the exciting circuit, which thereby reverses the fields of all four dynamos; the leads of the exciting dynamo being reversed at the same time, its fields thereby remain permanent.

The dynamos are connected to the switchboard by leads laid in moulding attached to the side of the concrete foundations, and running overhead from the end of the foundation to the switchboard where they connect by plug switches with leads to the lamp room on the third floor immediately underneath the switchboard of the operating room.

In shifting from one gang to another, in order to avoid interruption of current, the set to be put into service is first brought to the same potential as the working set, and then thrown into multiple with it, and the set which is to be relieved is then thrown open leaving the remaining set to furnish the current. The local and loop dynamos of the other gang are brought into service by means of the friction clutches.

On a large switchboard, 30 feet long by 6 feet 10 inches high, are mounted the regulating resistance boxes, voltmeters, reversing switches and steam guages. There are three high reading voltmeters for the series sets of dynamos, and three low reading voltmeters for use on the local and loop dynamos, and also for taking the reading on a single dynamo. Readings are taken from the 280 volt potential, and also from the exciting dynamo by which means any variation can be noted and corrected.

The lighting dynamo is provided with an ammeter and a potential indicator, also switches, fuses and other usual accessories. All test instruments are from the well-known Weston Electrical Instrument Co. of Newark, N. J.

A Bristol recording pressure guage registers the boiler pressure which is checked by an ordinary pressure guage. There are also pressure gauges for the heating system and the exhaust.

The lamp room is located on the third floor immediately below the main switchboard. The current from each potential lead is subdivided by passing through a number of sets of incandescent lamps which reduces the current to a maximum of about half an ampere for each line, there being a separate set of lamps for each line. The fourth and fifth potential currents pass through sets of three lamps in series, the second and third potentials through sets of two lamps in series, and the first potential through sets of single lamps. Each set of lamps is connected to battery discs on the main switchboard in the operating room. The usual horizontal battery bars on the back of the board are not used. Each battery disc supplies only one line. Notwithstanding these changes on the back of the board, all battery manipulations on the face of the board are carried out in the same manner as would be the case with continuous battery bars. Each horizontal row of battery discs is treated as a battery bar of a certain potential.

The operating room, located on the fourth floor, is 37½ feet wide by 125 feet long and 23 feet in height. It is well lighted by windows on all four sides and also by two ventilating sky lights in the roof. The roof is of the truss pattern, and is supported independently of the walls of the building by means of iron columns extending to the basement foundation.

The switchboard is located in the east side of the room and is 22 feet in length by 10 feet in height, and 8 feet deep, and is composed of seven sections. Five sections are each fitted with 50 wire standard W. U. spring jack switchboards accommodating 250 wires. Two sections are fitted with two loop jackboards, each accomodating 100 loops for switching, quadruplex and duplex sending and receiving local circuits and city loops.

All instrument wires are in Kerite cables run through the floor and carried along the ceiling below the operating room in wooden cleats attached to iron hangers.

The table equipment consists of 28 octette tables, 6 quartette tables and 7 Wheatstone tables. The table equipment is sufficient to accommodate 275 operators. The instrument equipment consists of 25 quad sets, 10 duplex sets, 3 Wheatstone sets and 115 single sets.

The building is provided with an elaborate system of pneumatic tubes, aside from the pneumatic tube service to the Merchants Exchange, and is thoroughly lighted with arc and incandescent lights, the Ward arc lamp being used on the incandescent circuits.

A steam elevator extends from the basement to the operating room. Some 3500 feet of new Kerite cable has been erected, covering all of the down town portion of their territory.

The installation has been carried out under the personal supervision of Mr. L. L. Summers, Assistant Electrician, W. U. T. Co., Chicago; Mr. H. S. Graber, Chief Engineer, St. Louis; and Mr. A. E. Van Tyne, Electrician of the St. Louis office, aided by a staff of able assistants. It is a model of excellence in telegraph engineering work.

NOTES ON THE DESIGN OF MULTIPOLAR DYNAMOS.[1]—II.

(*Concluded.*)

BY W. B. ESSON.

OUTPUT OF ALTERNATING CURRENT ARMATURES.

THE armature leads for alternators, though producing a cross magnetization, as in direct-current machines, raise no considerations, of course, as regards sparking. But on account of the greater proximity of the poles, and the greater stray field resulting, it is desirable to make the layer of copper on the armature core as thin, and the air gaps as short, as possible. As a consequence, probably, of the increased ratio of stray to useful field, the induction is less in the gaps of alternating than in those of direct-current machines. Some comparisons have been made of the output of direct and alternating machines of the same weight, but these, in the nature of things, must be misleading. The two types are quite unlike in their proportions, as Figs. 1 and 2 show, and no one would think of making them the same. Fig. 1 represents the magnetic system of a four-pole direct and Fig. 2 that of a twelve-pole alternating machine of the same output; and while it will be observed that the iron parts—core and yoke-rings—are much heavier in the former, it will be noticed that the copper in the magnet coils is much heavier in the latter. In fact, though the iron in the alternator is only 55 per cent. of that in the direct-current machine, the copper required is no less than 250 per cent. It is difficult, then, to understand what useful purpose is served by comparisons such as I have alluded to.

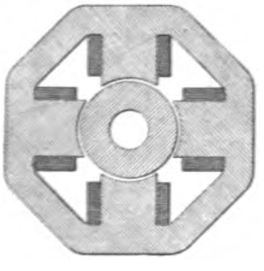


FIG. 1.

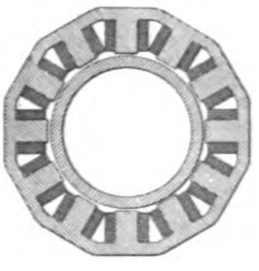

FIG. 2.

RELATION OF AIR GAP TO DIAMETER OF ARMATURE AND NUMBER OF POLES IN DIRECT-CURRENT MACHINES.

Having established the proportionality of the volume and diameter, it is easy to find the relation which must exist between the diameter and length of air gap for any particular angle of embrace, in order that sparking may not occur.

But, as is also seen from the equation, the gap required for any particular volume is proportional to the angle of embrace, and if we substitute for two poles a greater number, of correspondingly less angular width, working with an increased diameter and volume without a proportionally increased gap is made possible. This is where the advantage of the four, six or even eight pole machine comes in.

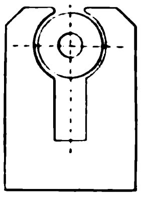

FIG. 3.

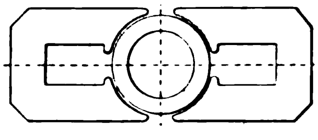

FIG. 4.

DIMENSIONS OF THE ARMATURE.

It has been observed that the output of an armature is proportional to d^2 L; and the induction being the same, the weight of the core for a given number of poles must be proportional to the output, the radial depth increasing directly as the diameter, so that a proportionally increased field may be carried. The number of poles being fixed, the weight of the core for a given output may be taken, therefore, as approximately constant, whatever the ratio of L to *d*.

The power wasted in hysteresis is proportional to the weight of iron magnetized, and to the number of reversals per second. The weight being inversely, and the reversals directly, as the number of poles, the power wasted is for a given output the same.

So much for the core; let us now consider the copper part. Taking Gramme-wound armatures having an interior opening equal to .66, or two-thirds of the core diameter, it is found—the output, speed, and temperature being predetermined—that the ratio of L to *d* may vary through a considerable range without making any great difference in the weight of copper or efficiency.

All the above facts go to prove that if there is anything to be gained, as regards the production of the field, by increasing the diameter of the armature and the number of poles, there is nothing, considering the armature by itself, to be lost by it. It may, in fact, be rather an advantage, because the weight of the iron core is reduced. It is true the peripheral velocity is increased; but this does not matter in the least, provided a certain limit is not exceeded. Opinions differ as to what the limit should be, some machines working at 50 ft. per second, others at 100 ft., and a few as high as 125 ft.

DIMENSIONS OF THE FIELD MAGNETS.

It will be apparent, from the foregoing considerations, that the employment of two or more than two poles for direct-current machines of moderate dimensions resolves itself mainly into a deliberation regarding the most economical shape to give to the field magnets.

I have said that for the prevention of sparking it is necessary that, the induction per square centimetre remaining the same, the air gap increases proportionally to the diameter, whether the space is necessary for conductors and clearance or not, but that the coefficient by which the diameter has to be multiplied to give the length of the gap necessary to prevent sparking diminishes directly as the pole angle. In comparing the magnetic system of a four or six-pole machine with that of a two-pole one, it is necessary to adopt dimensions for the armature in accordance with the considerations already mentioned; hence, if the two-pole armature had a length of core equal to one and a half times its diameter, in a four-pole one the length should be about half the diameter. The diagrams Figs. 3 and 4 show the cross sections of two such machines. The diameter of the four-pole armature is 1.4, and its length .5 times that of the two-pole one, consequently both machines give the same output. The weight of the two horse-shoe magnets in the four-pole machine comes to 56 per cent. of the weight of single horse-shoe magnet, which indicates in this particular case a considerable saving in wrought iron. In taking the copper weight it is necessary to bear in mind that this does not vary simply as the length of the wire if the machines are of the same efficiency, but as the square of the length; so in this particular comparison the copper on the two horse-shoe would be, roughly, 30 per cent. more than on the single horse-shoe, assuming the length of the air gaps to be the same.

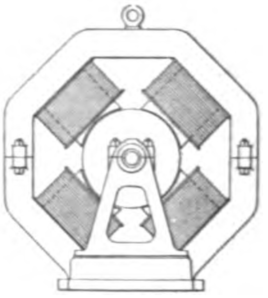

FIG. 5.

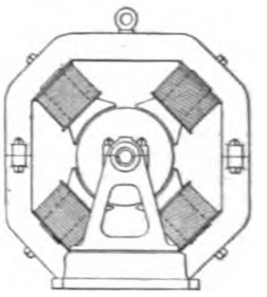

FIG. 6.

When we come to machines of a certain size, there is undoubtedly a gain in employing more than two poles, while very large machines become impossible of construction with two poles only. But to go beyond four poles in many cases would be a mistake, Increasing the poles always results in an actual increase in copper, unless at the same time the power spent in the gap is reduced, and this latter must be effected without reducing the thickness of the armature winding.

Having discussed the design of multipolar machines as influenced by both theory and practice, it remains to conclude this communication by calling attention to some of the ordinary forms of multipolar fields. The double wrought iron horse-shoe Fig. 4 is not very frequently used, being rather costly. Fig. 5 is a form designed by Gramme in 1885, and since adopted for cylinder-wound armatures by many makers, including Mr. Jasper, in Belgium; Mr. Brown of the Oerlikon Works, in Switzerland; and Messrs. Paterson & Cooper, in England. Fig. 6 represents a similar field in which the magnet cores are of wrought iron, fitted with cast iron pole-pieces, as used by Mr. Kapp. The decision as to whether cast iron or wrought iron should be used is arrived at in a very simple manner—by comparing the excess of copper required on one hand with the extra machining required on the other.

---

[1] Abstract of a paper read before the Institution of Electrical Engineers.

All these are examples of single magnetic circuits, where the lines of force from each pole remain undivided in their paths through the magnetizing coils; but in Figs. 7 and 8 are shown examples of double magnetic circuits, in which the lines from each pole take two paths through separate coils. Fig. 7 is a type of magnet used by Sautter-Lemmonier, of Paris, for Gramme-wound armatures, and by Cuenod-Sautter, of Geneva, for armatures having a Siemens winding as modified by Thury. It looks at first sight as if the weight of copper were not very different in the two types, but in this respect appearances are deceptive, for, as a matter of fact, the field of a four-pole machine made to Fig. 7 would require about 125 per cent. more copper than if made according to Fig. 6. It will be observed, however, that the magnet cores and pole pieces, which are made throughout of the softest wrought iron, are very light. In Fig. 8 the magnets are a series of wrought iron bars lying parallel to the armature, each fitted with a cast pole-piece in the middle of its length, and having two magnetizing coils, one on each side of this piece. It is a structure which may be frequently met with, though not precisely in the form shown, and the observations regarding the copper made with reference to Fig. 7 apply equally here.

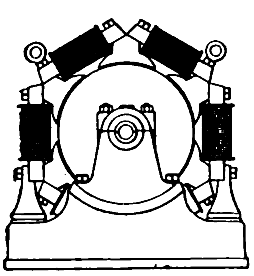

Fig. 7.

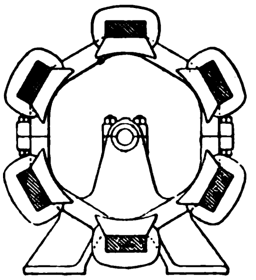

Fig. 8.

The fields of alternators may be similarly divided into those having single and those having double magnetic circuits; the former requiring, as in the fields of direct-current machines, much less copper than the latter. Amongst those having single magnetic circuits are the machines of Siemens, Ferranti, Mordey, Westinghouse, Elwell-Parker, and Paterson & Cooper. Mr. Kapp possesses the distinction of having the only alternator with double magnetic circuits.

BATHURST'S CROSS OVER BLOCK.

Any one who has had experience in the running of wires in buildings either as "cleat" or "molding" work, must have felt the need of a suitable device to facilitate and ensure a safe crossing of wires of different polarity, for, no matter how carefully the arrangement of the wires may have been thought out there must, and will, be points in the installation at which a "return" wire has to cross over, or under, a "leading" wire; and although the wires are drawn in the diagram as crossing without touching, this being usually shown by a small semi-circle, it will be in the experience of every electrician as to the number of these "crossings" that have been of an unsatisfactory and dubious character. In cleat work, perhaps a piece of asbestos paper has been put between the wires, and in molding work one may have been taken either at the back of the wooden molding on the bare brick or plaster, or passed exposed to view over the cover. We illustrate in the accompanying engravings an improvement, patented by Mr. Fred Bathurst, of Schenectady, upon the ordinary way of taking branches off mains and crossing wires in electric circuits.

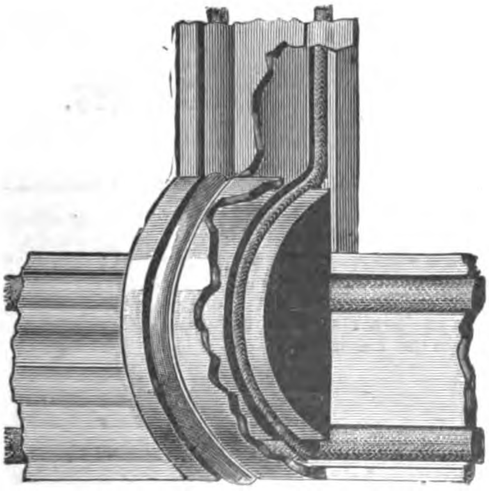

Fig. 1.—Bathurst Cross Over Block.

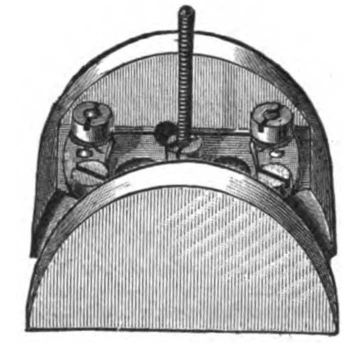

Fig. 2.—Bathurst Cross Over Block.

Fig. 1 shows the application of a wooden block to molding work, and Figs. 2 and 3 a porcelain block as arranged for the insertion of a fuse in the circuit, as will be the case where the crossing wire is a branch from a main. The blocks, which combine neatness with efficiency, were introduced in England a short time ago, and are slowly but surely finding favor there, but we predict that with our American enterprise and absence of conservatism and for old methods, their merits will soon be recognized by our electricians, and a ready market for them will follow.

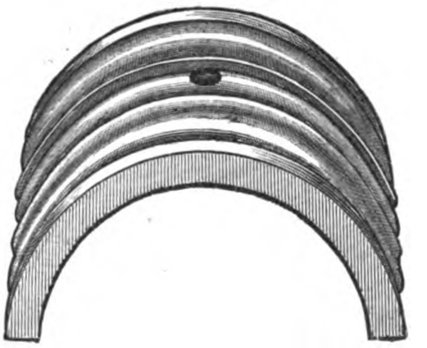

Fig. 3.—Bathurst Cross Over Block.

FRANKFORT EXHIBITION OFFICIAL JOURNAL.

By order of the board of directors of the international electrical exhibition in Frankfort, an official paper is to be published under the title of *Elektricität*. It is to appear in weekly issues, and will be edited by Dr. Max Quarck and H. Massenbach, engineer in Frankfort. It will be the mouthpiece for the official reports of all the particulars of the electro-technical exhibition. The journal will bring before its readers a history of the origin and course of the exhibition, a complete representation of the present state and prospects of electro-technics, an authentic report of the work of the juries and the consultations of the professional congresses which are to meet during the exhibition, as well as carefully selected, reliable reports and discussions on the exhibits. The *Elektricität Officielle Ausstellungszeitung*, will also contain original papers, detailed reports and notices, and will be illustrated by engravings, sketches, and plans. It will be published weekly, commencing on April 15th, and there will be altogether 30 issues, each having at least three sheets. When finished it is expected to form a worthy memorial of the present state of electrical science and of the international exhibition at Frankfort.

Mr. H. A. Loomis has been appointed superintendent of the Manitou Beach, N. Y., electric railway. About five miles of track are now laid, and the engines and boilers are in position in the power house.

Letters to the Editor.

OIL AS AN INSULATOR FOR HIGH TENSION TRANSFORMERS.

In the issue of the THE ELECTRICAL ENGINEER, of April 15, 1891, No. 154, you publish a letter, signed by Prof. Elihu Thomson, referring to your article in No. 153 on the use of oil in high tension transformers.

The tone of the letter would imply that I had encroached on a Patent, No. 428,648, issued in May, 1890; the claim in this patent is for the use of oil as a means of conveying the heat from the coils to the outer casing of the transformer, and not specially for insulating, as, no doubt, Prof. Thomson well knew that, as far back as 1880, Brooks employed oil for insulating purposes in a mode quite similar to that described in the patent above referred to.

I never claimed to be the first to use oil for insulating and have stated in my paper read in Frankfort-on-the-Main, February 9, 1891, and published in the *Elektrotechnische Zeitschrift*, No. 11, 1891, my opinion that Brooks was the first to advocate and use oil for insulating.

What I claim is, that I was the first to perceive and put into practice the idea that by means of oil it was possible to make commercial transformers for very high tensions; this occurred to me in October, 1889, in working out a project for transmitting 30,000 h. p. over a distance of 60 miles, and I am not aware that any one had made transformers in this way before that date, nor do I find that the patent No. 428,648 of Professor Thomson bears upon the fact.

As to any similarity between the forms of the transformers, the only published drawing that I have seen—that contained in the United States patent—is not clear enough to distinguish the arrangement, but I may state that transformers of the type shown in THE ELECTRICAL ENGINEER, No. 153, were constructed in the Oerlikon Works in November, 1889, and put to work in an installation in the beginning of 1890.

C. E. L. BROWN.

OERLIKON BEI ZURICH,
April 25, 1891.

Literature.

National Electric Light Association Twelfth Convention. August, 1890. New York. *Bartlett & Co.* 1891. Illus., 595 pp.

THIS handsome volume contains the full report of the proceedings of the National Electric Light Association, at Cape May, August, 1890. The papers presented at that time were numerous and valuable, and thoroughly deserving of preservation in this form. The volume is the best as to typography and binding issued by the Association and does great credit to the printers.

Universal Wiring Computer for Determining the Size of Wires for Incandescent Lamp Leads and for Distribution in General. By Carl Hering. New York, 1891. *W. J. Johnston Co., Ltd.* 44 pp. 5 x 8 in. Price, $1.

IN this work Mr. Hering has sought to make the labor of calculating the size of wires for electrical distribution as simple as possible and has availed himself of the graphic method for this purpose. The charts contained in the book cover a very wide range of conditions and will be found a useful aid to the electrical engineer. To the charts is added a series of wiring formulæ, and a clear explanation of the manner in which the formulæ are deduced, so that they may be used with intelligence. Tables of wire gauges, weights, resistances, etc., follow the charts, and a number of handy tables are added, by which the size of wire for a given number of lamps, under varying conditions, can be read off directly. The work is gotten up with the usual care exhibited by Mr. Hering, and will, no doubt, enjoy deserved popularity.

HANDY RULES FOR WHIST.

The Employer's Liability Assurance Corporation, Ltd., through Endicott & Macomber, Boston, Mass., have issued a tiny little folder containing ryhmed rules for whist. It will slip easily into the vest pocket or card case, and presents in a pithy poetical form, the principal points which will win at whist.

College Notes.

UNIVERSITY OF PENNSYLVANIA.

The Trustees of the University of Pennsylvania have decided to light the buildings throughout by electricity.

The electric lighting will be partly on the alternating and partly on the direct current system. Two 500-light 1000 volts, alternating and four 500-light direct current dynamos are to be employed. As with the boilers and engines, it is proposed to use several types of American machines. The two alternating dynamos will be connected to a separate switch-board, and so arranged as to run either singly or in parallel, or one may be run as a motor. The direct current machines will be compounded, but so arranged that by throwing a switch they become shunt machines. These will also be so connected to their switch-board as to run separately or in multiple. One alternating, and one direct, machine will be connected by belt to each of the compound engines; the remaining dynamos will be driven each by its separate engine. By this arrangement either dynamo or either engine may at any time of the day be used for experiment or instruction, as is the case with the boilers. This plant, in addition to the machines already belonging to the Department, and including the motors for driving fans, will be larger and more comprehensive than that of any other institution in the country. Students will have actual practice in the handling of the entire apparatus, and will be enabled to obtain a very considerable familiarity with the details and peculiarities of the systems of the principal American manufacturers.

The feeder wires, both alternating and direct current, will be carried underground. The arrangement of the lamps in the buildings will be made by the architects, Wilson Bros., who have also drawn the plans for the entire plant. The plant, when completed, will be under the immediate charge of a superintendent, to whom the officers of the department act as advising and consulting engineers.

It is believed, when the above plans are carried out, that the University of Pennsylvania, as regards its Mechanical and Electrical Engineering, will take the front rank among educational institutions in the completeness of equipment, and facilities for instruction, in those branches.

ROSE POLYTECHNIC INSTITUTE.

The Rose Polytechnic Institute, an advertisement of which appears in the present issue of THE ELECTRICAL ENGINEER, is one of three or four schools in the U. S. which are especially devoted to the education of Civil and Mechanical Engineers. One of the peculiar features of the Institute is the thorough and extensive "shop practice" of the students in Mechanical Engineering. Not only are machines designed and working drawings made, but actual construction is required and is made possible in extensive workshops, the equipment of which has cost over forty thousand dollars. H. T. Eddy, the new president, is well known as the Dean of the Faculty of the University of Cincinnati, and a great educator and organizer.

Society and Club Notes.

ELECTRICAL DEPARTMENT, BROOKLYN INSTITUTE.

At the last meeting of this section the following officers were elected: President, James Hamblet; first vice-president, Prof. S. Sheldon; second vice-president, W. D. Sargent; treasurer, R. W. Bayles; secretary, R. J. Murphy. Mr. Hamblet, thanking the members for his re-election as president, read his annual report, which showed the department to be active and vigorous, and one of the largest in the Institute.

Obituary.

WILLIAM J. CULL.

The death occurred recently of Mr. W. J. Cull, the superintendent of fire alarm telegraphs of the City of Albany. He was an old telegrapher, being at one time associated with the Hon. James D. Reid. He had filled the position named since 1875. His nephew, W. H. Cull, is electrical superintendent of the Albany City Railway.

Reports of Companies.

MEETING OF THE WESTINGHOUSE ELECTRIC & MFG. CO.

(*Special Despatch to* The Electrical Engineer.)

Pittsburgh, Pa., May 18, 1891.

The adjourned annual meeting of the stockholders of the Westinghouse Electric and Manufacturing Co. was held in this city this morning, in the Westinghouse building. There was not a very large attendance of the stockholders, probably for the reason that the result of the meeting had been anticipated by most of them. Mr. Geo. Westinghouse, Jr., president of the company, called the meeting to order and then requested that a motion to adjourn the meeting again for two weeks be offered. Mr. Westinghouse explained this suggestion by stating that the majority of the stockholders had hardly had the time to send their certificates of stock to the Mercantile Trust Co. of New York, and as it would be necessary to have the majority assent to the proposed plan of reorganization it would be better to wait until June 1. This suggestion was accepted, and the motion was passed unanimously.

After the meeting, Mr. Westinghouse stated, that so far he had not heard of a single opposing voice to the plan and he felt confident that everything would be settled satisfactorily within a few days. He urged the stockholders to send their shares of the stock in as soon as possible, in order to delay the matter no more than was absolutely necessary.

BELL TELEPHONE OUTPUT.

The instrument output of the Bell Telephone Company for the month ended April 20 and for the four months of the company's fiscal year is reported in comparison with last year, as below:

Month ended April 20.	1891.	1890.	Inc.
Gross	6,418	6,062	351
Returned	3,278	1,892	1,386
Net	3,135	4,170	*1,035
Since Dec. 21—	1891.	1890.	Inc.
Gross	22,367	18,881	3,486
Returned	12,839	8,042	4,797
Net	9,528	10,839	*1,311

*Decrease.

DIVIDENDS.

The Erie Telegraph and Telephone Company.—A quarterly dividend of one per cent. will be paid by check mailed to stockholders May 18th, that were of record at noon, Wednesday, May 6th. The Cleveland Telephone Company, the Northwestern Telephone Exchange Company, and the Southwestern Telegraph and Telephone Company, report for the three months ending March 31st, 1891, a

Gross income of	$202,398.65
Gross expense (including dividends paid)	199,186.27
Surplus	$3,297.38
SUBSCRIBERS.	
Number connected December, 1890	13,147
Added during the quarter	229
Total number connected March 31st, 1891	13,376
Proportion of dividends received by the Erie Telegraph and Telephone Company	$53,156.37
Dividend No. 30	48,000.00
Surplus	$5,156.37

Fort Wayne Electric Co.—The directors of the Fort Wayne Electric Company have declared a dividend of 75 cents per share, payable May 15, to stockholders of record May 9.

Skowhegan, Me.—The directors of the Skowhegan Electric Light Company have declared a semi-annual dividend of 3 per cent. upon the stock of the company, payable June 1st.

STOCKS AND BONDS.

Springfield, Mass.—At a recent meeting of the United Electric Light Company, it was voted to increase the capital stock from $300,000 to $400,000, and half of the new certificates will be issued June 10. The balance will be issued September 1.

The stockholders of the Southern New England Telephone Co. have ratified the action of the directors in bonding the company to the amount of $300,000 to secure its indebtedness.

ELECTIONS.

Attleboro, Mass.—At a meeting of the North Attleboro Steam and Electric Co., choice was made of the following board of directors: E. S. Horton, Geo. Demarest, L. W. Dillon, Peter Nerney and H. M. Daggett, Jr. Subsequently the directors organized by the election of Peter Nerney, president; C. T. Guild, treasurer, and P. E. Brady, clerk. The company is prosperous, every horse-power of its motor service being in use to-day and an increased demand for its arc and incandescent service presenting itself. Twenty arc lights, of the 52 thrown up by the town's foolishness, go into service in a single jewelry factory.

Putnam, Conn.—The Putnam Light and Power Company has elected the following officers: President, the Hon. J. B. Tatem; secretary and treasurer, A. W. Bowen; directors, J. B. Tatem, J. W. Manning, Orrin Morse, Dr. O. La Rue, S. H. Seward.

Utica, N. Y.—At the annual meeting of the Baxter Overland Telephone Company, all of the officers were re-elected, with the exception of Director Max Lehmann, who has removed to New York. Louis Friede was elected to fill the vacrncy.

New Haven, Conn.—At the annual election of the Southern New England Telephone Co. the following directors were re-elected: Morris F. Tyler, Lyman B. Jewell. A. Heaton Robertson, William E. Downes, A. W. Jillson, James English, A. O. Morgan, Samuel E. Merwin, Thomas Sherwin.

Detroit, Mich.—The Brush Electric Light Co., of Detroit, held its annual meeting May 12, 1891. $600,000 capital. Running 1,800 h. p. and doing well. Officers elected: Wells W. Leggett, president; Wm. C. Colburn, vice-president; Jas. L. Edson, treasurer: H. Leonard Wilton, secretary and general manager.

Appointments, Etc.

Mr. C. D. Paige has resigned as treasurer of the Stockbridge, Mass., Gas and Electric Company, and is succeeded by C. W. Johnson, and the office will remain where it has been. A. McLean, who has been in the service of the company for the past year, has been appointed general manager and superintendent of the plant and will have charge of all the practical part of the business. The Southbridge Gas and Electric Company is on a dividend paying basis, and is as well established a concern of the kind as there is in the state.

Mr. C. B. Martin, has been appointed manager of the telephone exchange of Binghamton, N. Y.

Financial Market.

QUOTATIONS ON ELECTRICAL STOCKS.

F. Z. Maguire & Co., Electrical Securities, of 18 Wall street, this city, report the following quotations of May 16, 1891, from New York, Boston and Washington.

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED MAY 12, 1891.

Accumulators :—

Secondary Battery, J. Emmner, Jr., 451,921. Filed July 9, 1889.

Consists in making either or both of the elements of aluminum and using any suitable active material.

Alarms and Signals :—

Electrical Signaling Device, C. J. Kintner, 452,026. Filed July 15, 1890.

A central station signaling system adapted for use in connection with the automatic individual signaling apparatus patented by Adin A. Hatch, Sept. 2, 1890, No. 435,983.

Visual Indicator for Fire Alarm and Other Purposes, M. G. Crane and F. W. Cole, 452,165. Filed March 7, 1890.

Relates particularly to visual signals to be displayed in sight of firemen or others whose attention is required.

Bell Striker, M. G. Crane, 452,166. Filed Nov. 17, 1890.

Employs electro-magnetic apparatus for controlling a bell striker actuated by other power.

Clocks :—

Clock Synchronizer, A. G. Wiseman, 452,239. Filed Dec. 17, 1890.

Synchronizing mechanism actuated by an electro-magnet, the armature of which is attached to a lever pivoted in a plane which is at the side of the centre of the face of the magnet and has a compound movement.

Conductors, Conduits and Insulators :—

Coupling for Electric Wires, A. M. Hunt, 451,933. Filed Dec. 29, 1890.

A metal sleeve having an internal diameter not less than the combined diameters of the wires to be joined and adapted by twisting to bind the enclosed wires together and to conform to their external surfaces.

Conduit for Electric Wires, T. T. LaPoint, J. H. Flanagan and C. A. Thompson, 451,941. Filed Dec. 30, 1889.

Conduit is composed of a cylinder of sheet metal firmly rivetted at the seam and dipped in a composition of asphalt, resin and fatty matters, an internal lining of hydraulic cement and an external wrapping of layers of tarred paper alternated with layers of a composition of asphalt, resin and fatty matter, and over all a layer of the asphalt composition.

Electric Insulator, S. Oakman, 451,950. Filed Aug. 17, 1889.

An insulator of the usual form of glass insulator but with the addition of a member forming an eye upon one side to receive a line wire.

Machine for Covering Electrical Conductors with Lead, L. W. Tracy, 451,960. Filed Aug. 4, 1890.

The pipe-forming chamber is constructed in a narrow trough shape with upwardly-flaring sides and ends and a bottom curved concentrically with the die and core bar projecting across its shorter axis.

Process of Treating Conductors, J. B. Williams, 452,091. Filed July 11, 1890

The conductor is surrounded by a dielectric arranged with intermediate air spaces; the dielectric is raised to a suitable temperature when warm dry air is passed through the air spaces, the air being kept under pressure in the air spaces.

Wire Clamp, R. M. Jones, 452,185. Filed Dec. 17, 1890.

For linemen's use.

Electric Cable, W. A. Conner, 452,340. Filed July 24, 1890.

Wires are covered with saturated fibrous material arranged to form an open mesh providing air spaces.

Electric Cable, W. A. Conner, 452,341. Filed July 24, 1890.

Designed to prevent the spreading of moisture that may enter the cable at any point. The wrapping surrounding the insulated wires is omitted at definite intervals along the length of the cable; a sealing material is applied to impregnate and fill the core at the points of omission of the wrapping; the lead sheath is closely compressed round the core where it is impregnated with the sealing material.

Electric Cable, W. A. Conner, 452,342. Filed July 24, 1890.

Similar to No. 452,341 above.

Dynamos and Motors :—

Brush Holder, H. H. Blades, 451,909. Filed Aug. 14, 1890.

Designed to permit the position of the holder with respect to the commutator to be reversed without removing any of the parts from the supporting shaft or spindle.

Self-Controlled Motor Switch, G. H. Whittingham, 452,151. Filed April 25, 1890.

For simultaneously closing or opening communication between the main or working circuit and two branch circuits, the one including the field and the other the armature of the motor.

Electric Motor, D. J. Chisholm, 452,214. Filed Sept. 27, 1890.

A motor of the type employing a series of stationary magnets around its periphery and a system of revolving magnets within.

Electric Reciprocating Engine, C. J. Van Depoele, 452,296. Filed June 26, 1889.

A continuous current motor. Consists of two working circuits, a reciprocating motor having two coils, one in each working circuit, a magnetic piston, means for simultaneously increasing the current in one coil and decreasing it in the other.

Galvanic and Thermo-Electric Batteries :—

Galvanic Battery, G. C. McCullough, 451,948. Filed Sept. 3, 1890.

Has a double set of elements so arranged that one set may be used while the other is permitted to rest,

Primary Battery, W. Hanson, 452,303. Filed Feb. 4, 1891.

Relates to means for supporting the porous cell and electrodes upon a wooden frame at the top of the jar.

Lamps and Appurtenances :—

Drop for Electric Lamps, W. E. Dow, 451,996. Filed March 22, 1890.

An adjustable hanger.

Holder for Portable Electric Lamps, W. W. Savage, 452,288. Filed Feb. 20 1891.

When in the holder the weight of the lamp keeps the circuit open. Its removal closes the circuit.

Incandescent Electric Lamp, W. M. B. Keen & W. F. Haarmann, 452,305. Filed June 19, 1890.

Relates to the mechanical construction of the switch and socket.

Incandescent Lamp Socket, W. M. B. Keen, 452,306. Filed Sept 15, 1890.

Details of socket and switch.

Measurement :—

Electric Meter, H. W. Miller, 452,276. Filed Nov. 21, 1890.

Patented in Great Britain, Oct. 29, 1890, No. 17,327. A clock-work meter with differential gear actuating the register and controlled by a coil through which the current to be measured, or a part of it, flows.

Electrical Measuring Instrument, E. Weston, 452,326. Filed July 8, 1890.

A potential instrument. Consists of a coil rotary on its diametrical axis in the field of force of a magnet and disposed between the poles of the latter; the frame supporting the electro-magnets, their cores and the pole-pieces constitute a single magnetic structure.

Medical and Surgical :—

Surgical Electrode, J. H. Gunning, 452,230. Filed Nov. 20, 1890.

A bi-polar electrode, forming component parts of the instrument itself, and adjustable to vary their distances apart.

Electric Belt, C. D. Williams, 452,250. Filed Jan. 17, 1891.

A belt containing a series of galvanic cells.

Metal Working :—

Electric Rivetting Apparatus, E. E. Ries, 452,042. Filed June 25, 1889.

Details of apparatus for practicing the invention shown in the same inventor's patent of May 14, 1889, No. 403,374.

Miscellaneous :—

Fusible Cut-Out for Electric Connections, W. E. Dow, 451,997. Filed Dec. 4, 1890.

Especially applicable to electric lamps suspended from a drop capable of being raised and lowered.

Electro-Magnet, C. E. Lipe, 452,008. Filed Nov. 20, 1889.

Uses wires of rectangular sections to save space.

Apparatus for Heating by Electricity, C. Zipernowsky, 452,056. Filed Sept. 16, 1890.

Two conducting bodies are so arranged relatively to each other that an imperfect contact of high resistance shall exist between them.

Coin Operated Machine, W. H. Ashwell, 452,068. Filed Nov. 12, 1890.

Employs electro-magnetic releasing mechanism.

Thermal Cut-Out, G. H. Whittingham, 452,152. Filed Oct. 18, 1890.

Details of a fuse cut-out.

Combined Coupling and Cut-Out, J. D. F. Andrews, 452,173. Filed Oct. 27 1890.

Patented in Great Britain Dec. 18, 1889, No. 20,387. Combines a switch and fusible cut-out.

Gas-Engine Attachment, M. M. Barrett, 452,174. Filed Jan. 7, 1891.

An electric ignition device for the combustion chamber.

Railways and Appliances :—

Motor Truck, F. M. Lechner, 451,942. Filed July 23, 1890.

A motor truck for mining machines. Tool operating mechanism is mounted on the truck together with the motor.

Electrically Propelled Car, S. H. Short, 451,980. Filed Nov. 6, 1890.

Claim 1 follows:

The combination, with a car, of an electric propelling-motor comprising an armature mounted on and directly secured to a car axle, and non-rotative field magnets mounted on springs independently of the said armature.

Mounting for Electric Car Motors, S. H. Short, 451,981. Filed Dec. 1, 1890.

Armature is mounted directly upon the car axle; field magnets are directly journaled on the axle; a connection with side bars connects the pedestals and journals boxes of the two car axles.

Electric Railway Signal, W. C. Walter (deceased, S. L. Walter, Executrix), 451,999. Filed Nov. 23, 1889.

For intercommunication between vehicles or trains operated on the block system.

Driving Mechanism for Electric Motor Cars, S. H. Short, 452,005. Filed Nov. 1, 1890.

Employs a ring armature mounted axially upon a driving axle and non-rotative multipolar field magnets, the pole pieces of which are arranged to produce a field of force crossing the armature parallel to its plane.

Motor Car for Electric Railways, S. H. Short, 452,035. Filed Nov. 26, 1890.

Armature mounted directly on a driving axle; the field magnets are directly journaled on the same axle and a connection is made with another car-axle which holds the field-magnets from rotating.

Machinery for Propelling Electric Cars, S. H. Short, 452,036. Filed Dec. 9, 1890.

A single reduction system.

Electric Wire Suspender, C. A. Lieb, 452,017. Filed Nov. 8, 1890.

A trolley wire suspender.

Method of Braking Trains, E. E. Ries, 452,041. Filed Oct. 4, 1888.

Supplements the mechanical brake by increasing the friction between the wheels and rails by the passage of electric current.

Automatic Railway Signaling Apparatus, S. J. Doucet, 452,072. Filed Oct. 22, 1890.

Employs one electrically continuous rail and one having insulated sections. Alarm on board a train is put in circuit by contact brushes carried on the car.

Electric Railway, M. W. Dewey, 452,099. Filed Dec. 20, 1890.

Combines an induction and a conducting system. The induction system intended to be used on those parts of roads running through cities where trolley wires are impracticable. The invention consists broadly in an electrical railway having a portion equipped with a conduction system and another portion equipped with an induction system.

Electric Railway, F. O. Blackwell, 452,160. Filed Nov. 23, 1888.

Relates to an underground conduit system, and consists mainly in details of construction for the conduit and conductors.

Electric Car Motor, J. Christiansen, 452,176. Filed May 21, 1890.

Relates to the mounting of motors upon electric locomotives and to their connection with the driving axles.

Trolley Stand, R. M. Jones, 452,186. Filed Dec. 29, 1890.

A spring trolley stand with a revolving or oscillating base.

Railway Signaling Device, J. C. O'Neil, 452,281. Filed June 30, 1890.

For road crossings and similar service.

Telegraphs :—

Printing Telegraph, E. Pope, 451,951. Filed Feb. 18, 1888.

Receiver operates after the manner of a typewriter.

Telephones and Apparatus :—

Automatic Toll-Box, I. H. Farnham, 451,922. Filed Feb. 13, 1891.

A nickle-in-the-slot telephone call box.

TRADE NOTES AND NOVELTIES

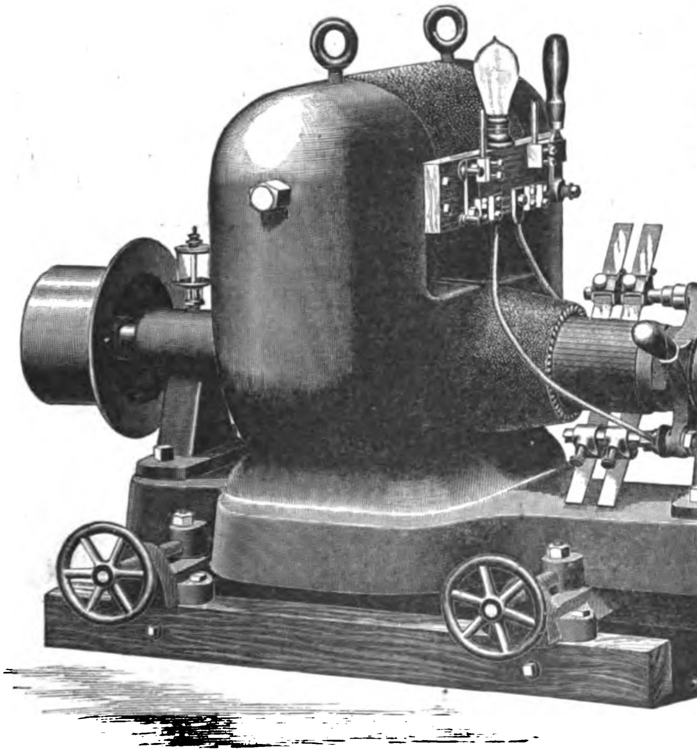
AND MECHANICAL DEPARTMENT.

Advertising is always interpreted as a sign of life, activity and progress. Dead men don't advertise.

THE HOWARD DYNAMO.

It will be readily conceded that a good dynamo, which may be had at a reasonable price, one with a high electrical efficiency that will cost little for repairs, and will regulate well, built with all the parts interchangeable, so that the armature, field magnet, commutators, etc., may, in case of necessity, be replaced with promptness and at the lowest possible cost, leaves but little to be desired.

The Howard dynamo, shown in the accompanying illustration, is claimed to possess all these advantages. The field magnet has but one magnetic circuit of low resistance, and but one coil, having both shunt and series windings, magnetizes the field. The pole pieces consist of massive castings of charcoal iron. The armature is of the drum type, and is wound with flat bars of copper, in order that, while keeping the distance as short as possible between the pole pieces and the core, the number of turns and the cross section of the copper shall be sufficiently great. The armature of a 300 light machine has 80 turns, with a resistance of .02 ohm, while the resistances of the shunt and series coils of the field are 19 ohms and .008 ohm, respectively.



The Howard Dynamo.

These machines are manufactured by Messrs. Hiram M. Howard & Co., of Cincinnati, O., and are built in twelve sizes, ranging in capacity from 10 to 500 lights. As motors they are wound for 110, 220, and 500 volt circuits, and develop from ⅛ to 35 h. p. Both motors and dynamos have been installed in various parts of the country, and are proving highly satisfactory in operation.

THE WIGHTMAN ELECTRIC MANUFACTURING COMPANY.

The above company, of Scranton, Pa., report to us that the recent fire in that city, in which the People's Street Railway Car house was destroyed, did not in any way damage them. On the contrary, it caused the People's Company to place with them an order for ten complete double-motor (new S. R. Motor) car equipments, all of their own manufacture. This, together with the six double-motor equipments to go to Easton, Pa., (all of these equipments to be delivered within the next sixty days), makes them very busy. Their factory is now running day and night. They now have orders booked for thirty five complete car equipments, and the prospects for a large and flourishing business are very favorable.

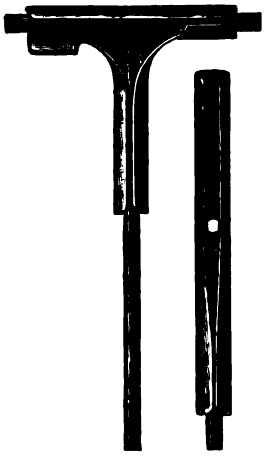
In the fire in the People's Car house, thirty-three cars—twenty five of which were equipped with double-motors—were totally destroyed; but thirteen cars, which, at the time of the fire, were standing on sidings outside the car house, were saved from the flames; the car house was reduced to ashes. The thirteen cars that escaped the flames, together with two cars fitted up with the two motors which the Wightman Co. have lent them, gives the People's Company fifteen serviceable cars; so that the system is by no means entirely crippled. The cars and car house were insured for $125,000, and that amount will nearly cover the damages.

DR. ARON'S ELECTRIC COUNTERS.

The representative of Dr. Aron in this country, Mr. F. Hackenthal, of No. 21 Beekman street, this city, has decided to temporarily close his office in this country. This, however, will not interfere with the delivery of the well-known Aron meters to the trade. All inquiries may hereafter be addressed to Prof. Dr. Aron, Lutzow Str., 6, Berlin, W., Germany.

BURT AND TOBEY'S ELECTRIC WIRE COUPLING.

The convenience of application of these couplings, which are shown in the accompanying illustration, especially adapt them to the use of wiremen, as they require for their adjustment only a pair of ordinary bell hanger's pliers. They make a perfect electrical, and a very strong mechanical, connection, and are so simple that they can be very cheaply made.



Burt & Tobey's Wire Coupling.

These couplings are made of both brass and copper, tinned for convenience of soldering, and do not materially increase the size of the wire. The sole agency is held by the Rhode Island Telephone and Electric Co., 13 Mason St., Providence, R. I.

SOUTHERN ELECTRIC CO.

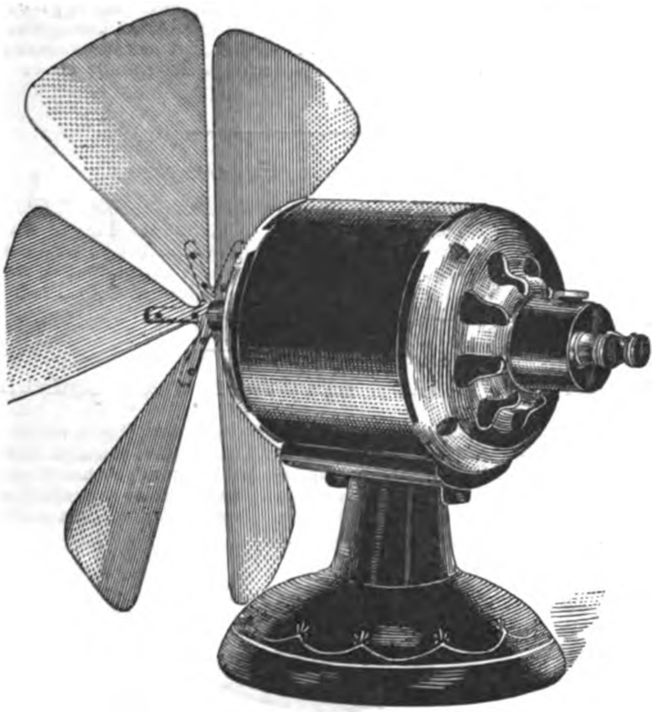
Under the personal management of Mr. J. F. Morrison, the Southern Electric Company, of Baltimore, is doing an increasingly thriving business. Mr. Morrison has taken hold of a number of new specialties and will push them on the market with his well-known vigor. Baltimore is a most excellent distributing point for electrical supplies and one that has thus far been almost neglected. This is changed now and it will no longer be necessary for our Southern friends to send to New York, Boston and elsewhere for supplies, which are now being carried in stock by the Southern Electric Company.

ENGINEERING EQUIPMENT CO.

Since removing to their new quarters in the Central Building, 143 Liberty street, the above company have issued two handsome, colored circulars, one relating to the Habirshaw wires, cables, etc., and the other to the indurated fibre pipe for electric conduits. The Habirshaw folder gives a complete list of prices, etc.

THE WAGNER ALTERNATING CURRENT MOTOR.

Owing to the great number of electric lighting stations now using the alternating current, a great demand has arisen for alternating current motors of small power, for driving fans, sewing machines, dental lathes, etc. A novel little motor for this purpose, has recently been brought out by the Wagner Electric Manufacturing Co., of St. Louis. As will be seen from the accompanying engraving, this motor is exceedingly compact and substantial in construction. The field is of the form known as iron clad, and admits of the shortest possible magnetic circuit, and the brass end pieces carrying the bearings and brushes are designed to protect the armature, commutator and brushes as much as possible, but are readily removed when necessary. The armature and commutator are built so as to practically eliminate sparking, and the brushes, which are of carbon and self-feeding, need no attention or adjustment, and require replacing but once in two months if used continuously. To renew the brushes it is simply necessary to remove the screw caps serving as binding screws, when the brushes and springs readily drop out. The bearings are self-oiling, and require no more attention than the brushes.



Wagner Alternating Current Motor.

The motor shown is rated at $\frac{1}{10}$ h. p., and runs a six bladed 10 inch fan with a pitch of 80° to 85°, 2,000 revolutions per minute, with an expenditure of 100 watts of electrical energy. The heating of the armature and fields is less than in most direct current motors, the rise in temperature never exceeding 20° C., above the surrounding atmosphere. These motors can be furnished of $\frac{1}{10}$, $\frac{1}{4}$, and $\frac{1}{2}$ h. p., for pressures from 50 to 110 volts for either alternating or direct currents, and furnished with fan or properly mounted for sewing machine or dental work. Patterns are now being made for a 1 h. p. motor which will run at constant speed with any load up to its rated capacity. This larger sized motor will be admirably adapted for pumping church organs, running small elevators, and a large variety of power work.

SHORT ELECTRIC RAILWAY CO.

The Short Electric Railway Company is putting a strong and energetic force of salesmen into the field for the purpose of covering territory to an extent that they have not yet done. They are securing some of the best trained railway agents in the business, and within a very short time the company expects "to be in at the death" on every street railway contract.

PERFORATING A BELT.

Chas. A. Schieren & Co. recently gave the Owensboro, Ky., Electric Light Co. the privilege of perforating a belt that gave them considerable trouble. Under date of May 8, the Owensboro people wrote as follows to the firm: "We have perforated the belt and are more than pleased with it; we used to have to run it so tight it was very near impossible to keep the journals cool; it now runs very slack and without waving or flopping. When we want more belts shall certainly use your perforated."

THE EDISON PHOTOPHONOKINETOGRAPH.

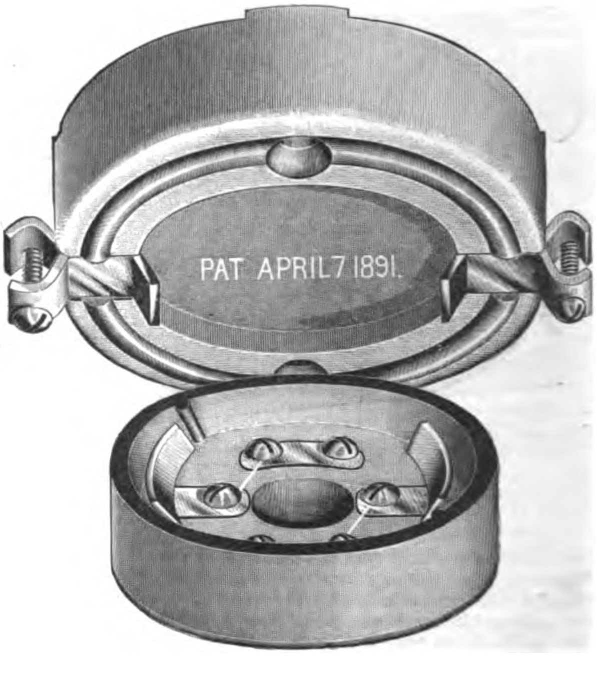
A dispatch from Chicago May 12, says: Thomas A. Edison was asked to-day if had an electric novelty in store for the Columbian Exposition. He said:

"Well, I have a thing in view, but the details are yet somewhat hazy. My intention is to have such a happy combination of photography and electricity that a man can sit in his own parlor and see depicted upon a curtain the forms of the players in opera upon a distant stage and to hear the voices of the singers. When the system is perfected, which will be in time for the fair, each little muscle of the singer's face will be seen to work, every color of his or her attire will be exactly reproduced, and the stride and positions will be as natural as those of the live characters. To the sporting fraternity I will state that ere long this system can be applied to prize fights. The whole scene, with the noise of the blows, talk, etc., will be truthfully transferred. Arrangements can be made to send views of the mill *a la* stock and race ticker."

Speaking of this the other day in Brooklyn, Mr. Edison said: "I make forty-six photographs a second on a moving sheet and by exhibiting this sheet moving at the same speed the scene is reproduced. I had a man sing into a phonograph the other day and I photographed him by this process as he was singing. Then I gave a concert. The phonograph reproduced the singing and the kinetograph reproduced all his motions and gesticulations."

NEW PERKINS CUT-OUT.

We illustrate in the accompanying engraving a new form of ceiling cut-out, which possesses some novel features. The base of the cut-out is made of porcelain with only two brass pieces attached to it, to form the binding posts for the main wires and the contacts for the cap. The cap is also made of porcelain, and has two brass lugs connected through fuse wires to the terminals of the lamp cord, which dovetail underneath the contact pieces on the base, when in position. The action is extremely simple, as there are no screws to be tightened when putting in place, the cap being held in the groove, and by a slight turn of the hand the contact is completed, the dovetails making a perfect rubbing electrical contact. The cut-outs are manufactured solely by the Perkins Electric Switch Company, of Hartford.



PAT APRIL 7 1891.

The Perkins Ceiling Cut-Out.

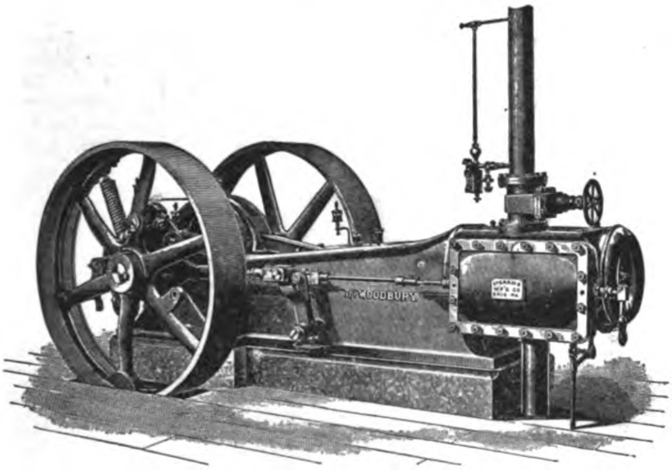
POSTAL TELEGRAPH CO. IN SAN FRANCISCO.

The growth of the business of this enterprising company has necessitated the removal of its San Francisco headquarters to the commodious new building at 582–586 Market street. This new building is one of the ornaments of the city; it is of granite and brick, with steel beams and copper roof, and is claimed to be thoroughly fireproof. The furniture is of antique oak, and the operating tables are of black walnut. No expense has been spared to make it perfect in all details.

THE WOODBURY HIGH-SPEED STEAM ENGINE.

We illustrate in the accompanying engraving the latest type of the Woodbury engine, designed by Mr. Daniel A. Woodbury, of Rochester, N. Y., and built by the Stearns Manufacturing Co., of Erie, Pa,

In cross section the frame is a tapering box, wide at the base, and heavily flanged at the top and bottom, the top flanges extending from the hood formed at the cylinder end, in a direct line to main bearings. At the crank end, the frame widens out to afford an unyielding support to the journals, and the top flanges also become wider towards the boxes, the latter being cast with the frame.



The Woodbury Automatic Engine.

The governor is of that class in which the valve closure is effected by moving the eccentric across the shaft. The movement of the eccentric is operated by centrifugal weights, the centripetal force being furnished by a single spiral spring. The direction of the pull of the spring is such as to bring the bearings upon the pivot pins always on the same side, whether the weights be moving outward or inward, thus avoiding all lost motion and rattling due to either wear or loose fitting.

The valve employed is of the adjustable type and balanced by means of a relief plate, thus taking the steam pressure off the valve and eliminating all valve friction. This leaves the governor free to act upon the valve and to change the lead with change of load in the shortest possible time.

The shaft and crank pin are formed with the cranks in one solid steel forging, and the construction is such that the counterbalancing discs can be readily removed and replaced in their original position; this allows of easy access to the pin which can then be trued up in a lathe, when necessary.

The relative weight of counterbalance to that of the reciprocating parts has been determined by a series of experiments throughout the entire range of speed, and with changeable counterweights. The proportions adopted are such as to secure perfect smoothness of action and an entire absence of vibration under the different conditions of load, speed, and steam pressure. The engines are tested for this quality by loosening the foundation nuts, and running up to speed, with the belt off. With the proper amount of counterbalance, no vibration or tendency to longitudinal movement is shown, the engine running as steadily as when bolted down.

The lubrication of all the moving parts has been thoroughly provided for, and the best materials and workmanship employed in the construction of these engines, which have already been introduced in a large number of electric light stations.

THE LLOYD AND PAXTON STORAGE BATTERY.

Electric railway managers, while expressing a preference for a car which will be self-propelling, have heretofore looked with suspicion on storage battery traction on account of the great cost of the batteries and their comparatively short life. In seeking to overcome this difficulty and also to provide a cell which shall have a high rate of discharge, Lloyd & Paxton, Ltd., of 2 Wall street, this city, are now ready to supply a cell which shall fulfill all the requirements, not only of street car service, but which is also eminently adapted for electric lighting. The grids of these cells are made of pure lead without the slighest imperfection. A large number of perforations are used, all containing exactly the same quantity of active material, and the plugs are firmly held in place by the concave section of the walls of the grid.

Starting out with the object of producing a cell at as low a cost as possible, the company has perfected a machine which makes the lead grids at the rate of 6,000 plates per day, and with the regularity of an envelope machine. On account of the large number of perforations, a large surface contact is established between the grid and the active material, and the even distribution of the metal of the grid results in equal electrical action over its entire surface. This machine is so constructed that it can make plates of any thickness from 1-16 of an inch to ½ inch, thus allowing of any type of cell being made, such, for instance, as a lighting battery with heavy plates.

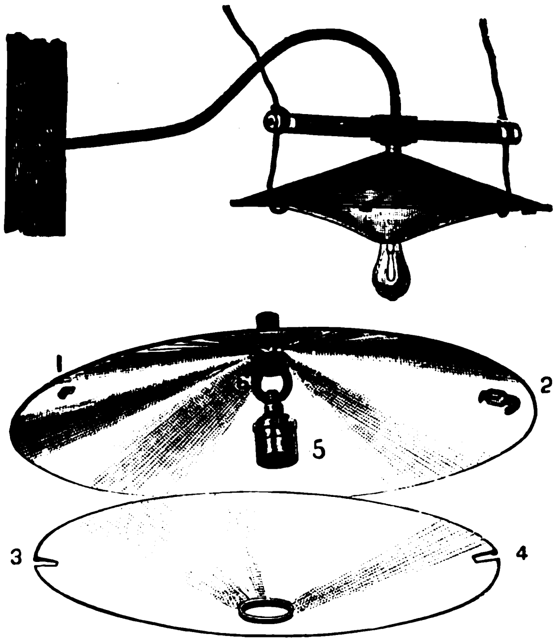
A cell of the railway type having a capacity of 175 ampere hours weighs only 25 pounds, and can be discharged at the rate of 100 amperes for one hour without dropping below 1.9 volt. The normal rate of delivery, however, is 50 amperes. This gives the very high capacity of .8 ounce of active material per ampere hour. This high rate of delivery is evidently a most valuable feature in connection with storage battery traction, as a motor propelling a 16 foot car frequently calls for nearly 150 amperes at starting and in climbing a grade of four per cent. The positive elements are calculated to last six months in railway service, and the negatives fully 18 months. The company propose to sell the cells at $5 a piece, and to buy back the old lead when the cell is practically worn out.

FIREPROOF LAMP CORD.

As the Boards of Underwriters in some states have condemned the use of any lamp cord that is not fireproof, the Central Electric Company, of Chicago, are offering a cord with an absolutely fireproof covering. They have already had large sales of this cord, and predict that before long it will drive all inferior articles out of the market.

THE "CLIPPER" STREET HOOD.

This hood consists of two pieces, the hood seventeen inches in diameter, and the reflector. These parts are seamless and made from spun zinc so as to withstand the influence of the weather. The hood is finished in green and the reflector in white enamel to procure the greatest efficiency in light. The fastenings consist of two hooks, one of them stationary and the other adjustable, and can be worked with one hand. These shades are furnished for either one light or a cluster, and do not require any tools to put them up. They are manufactured by The Illinois Electric Material Co., of Chicago. The cut represents the hood half open so as to show working portions. 1 is the hook; 2 the sliding hook; 3 and 4 the clip; 5 the socket, and 6 the bushing.



The "Clipper" Street Hood.

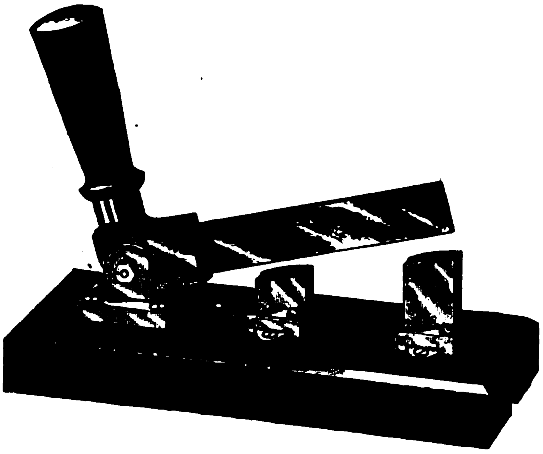
THE BRYAN FARADIC BATTERY.

This battery, which is one of the products of the Bryan Electrical works, of Springfield, Mass., is manufactured exclusively for physicians' use. The case is of walnut and the cell of hard rubber. More than 9,000 of these instruments have been sold to physicians over the United States, and are all giving satisfaction.

THE WIRT KNIFE SWITCH.

We illustrate a pattern of knife switch designed by Chas. Wirt, differing in many respects from the ordinary switches of this class. It is a double break and is so constructed that the knife cannot jar out of position, either closed or open.

No binding posts are used, the connections are made on the back by powerful clamps which are closed with screws from the front. The wires can be secured after the switch has been placed on the wall.

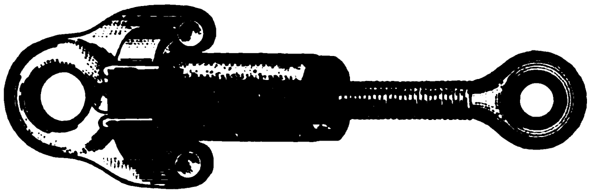


The Wirt Knife Switch.

These switches are made in all sizes, with slate or mahogany bases, by the Electrical Supply Co., 171 Randolph street, Chicago.

A NEW FORM OF MICA INSULATOR FOR SPAN WIRES.

Much difficulty has been experienced by the electric street railway engineer in thoroughly insulating the trolley wire from the poles. It has been found necessary, by experience, in addition to insulating the trolley wire from the span wire, to insulate the span wire from the pole, and we take pleasure in illustrating in the accompanying engraving a new form of mica insulator which has the double advantage of being a combined span insulator and turn buckle for tightening the span wire. The method of using the insulator is as follows: In setting up a span, the wire is cut off to the proper length, and both ends are attached to the eye-bolts of the insulators (two being used for each span), one of the eye-bolts being unscrewed from its case. The end of the span wire attached to the complete insulator is then hung up by means of the eye-bolts to the pole clamps provided, and the other insulator, without the eye-bolt, is hung up on the opposite pole. With an ordinary tackle the span wire is then tightened up until the eye-bolt enters the insulator, and the whole span can then be tightened by screwing up with a wrench. In this way spans can be put up in half the ordinary time, and a thoroughly insulated trolley wire is secured. The strength of these span insulators is sufficient to break a No. 2 B. W. G. span wire without injury to the insulator. They are manufactured exclusively by the Gould & Watson Company, 34 Hartford street, Boston. A number of them have just been put up on the Brooklyn City Electric Railway, Brooklyn, N. Y.



Gould and Watson Mica Span Wire Insulator.

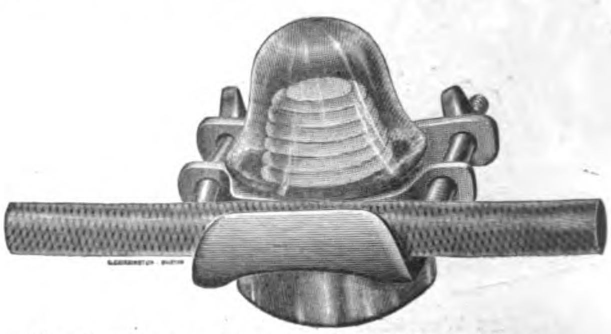
Clay, Pepper & Register have moved into new offices in the Provident Building, Chestnut and Fourth streets, Philadelphia, where they will have more room and better facilities for attending to their consulting and construction business as electrical engineers.

SOUTH LAKEWOOD PARK.

Pine & Maguire, 18 Wall street, who are the agents of the South Lakewood Park Co., in which so many electrical men are interested, have issued a very pretty and tasteful brochure describing and illustrating the property. In view of the enormous success of Lakewood, there seems no good reason why South Lakewood, its suburb, and a place superior in many of its attractions, should not soon enjoy like popularity and prosperity as a Northern Florida.

THE PETTINGELL ANDREWS FEEDER WIRE HOLDER.

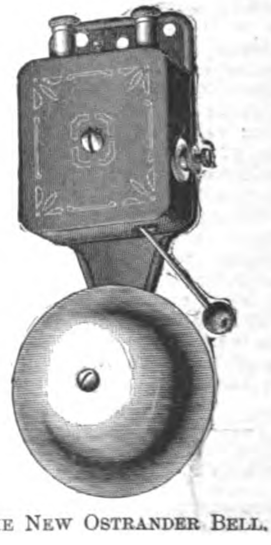
We illustrate this week a novelty in the shape of a new form of feeder wire holder, specially designed to tie large feeder wires to the insulator, as shown, without the necessity of the old tie wire, which takes time and labor, and is extremely apt to damage the insulation. This holder is much cheaper than tie wires, holds the cable or wire in a firm and secure grip, saves labor, time and money, and absolutely prevents any abrasion of the insulation, thereby preventing loss of current. It is manufactured exclusively by the Pettingell Andrews Company, of 196 Summer street, Boston.



The Pettingell Andrews Feeder Wire Holder.

THE OSTRANDER BELL.

The accompanying illustration shows an admirable, new iron box electric bell, manufactured by Messrs. W. R. Ostrander & Co., of 195, 197 Fulton street, this city. The armature has bottom and side adjustments, and is pivoted in such a manner that, although working very freely, it is impossible for the points to get out of contact. The bell can be adjusted to ring on one cell of battery. **The contacts are made of platinum wire, and the armature spring is of phosphor bronze.**



The New Ostrander Bell.

The works are all in the box, held by a centre screw to the back plate which may, therefore, be permanently fastened to the wall.

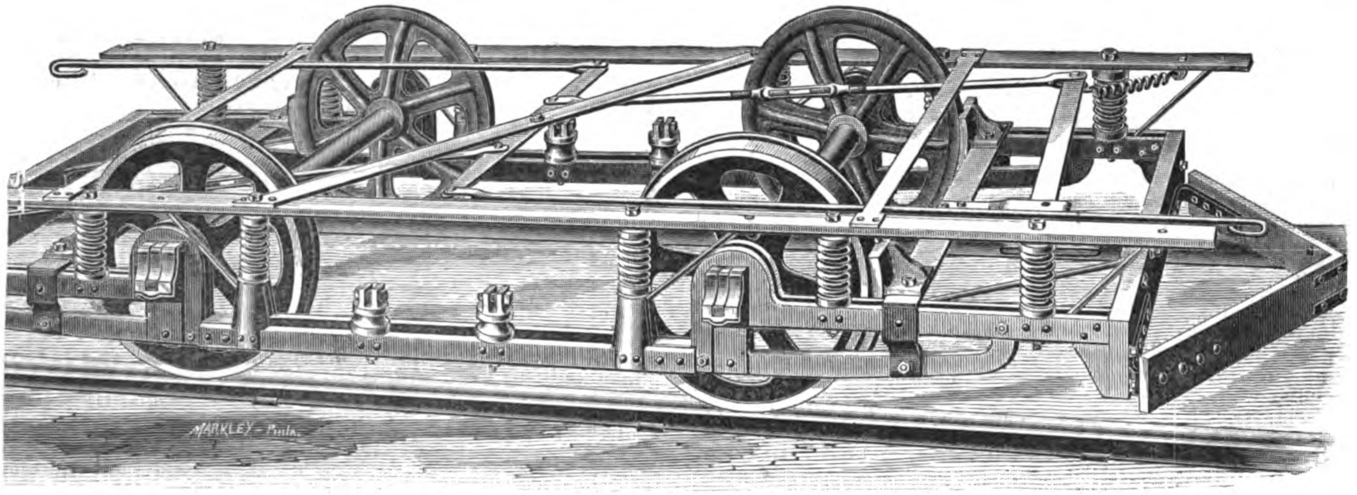
The Thomson Electric Welding Co. is building three large welders for the Johnson Co., at Johnstown, Penn.

MAINE ELECTRIC IMPROVEMENT CO.

Messrs. Alex. Henderson and Thomas J. Fay, late of the Hunt Engineering Co., of Brooklyn, N. Y., have combined their efforts, in connection with Mr. James L. Doolittle, a well-known banker and financier, of Brunswick, Maine. The result is a new and well equipped engineering company, under the name of the Maine Electric Improvement Co., incorporated under the law of the state of Maine, the home office of which is at Brunswick, with Mr. Henderson, as president, and Mr. Doolittle as secretary and treasurer; with general business offices in the Electrical Exchange building, corner Liberty, Washington and Cedar streets, New York city, with Mr. Fay as general manager. This company will make a specialty of furnishing plans, specifications, electrical tests and reports on proposed plants, and will also do a general engineering business, while from time to time they will place at the disposal of the public many new and interesting specialties of their own manufacture.

THE ROBINSON ALL STEEL ELECTRIC TRUCK.

In studying out the problem of the best method of constructing a truck for use on electric cars, whereby oscillation would be reduced to a minimum, the designer of the one shown in the accompanying illustration became convinced that some form other than that of the cast iron yoke and pedestal would have to be adopted. Constant observation and experience, says the *Street Railway Gazette*, taught him that these yokes, riveted to the side frame, in order to support the extreme ends of the car body, must, necessarily, be so heavy that the truck was usually cumbersome, and the rivets, which held the side bars to the yoke, were located in the most vital part of the truck, which latter frequently pounded itself to pieces, the only alternative being the use of a truck so heavy that extra power was really required to run it.



MARKLEY-Phila.

THE ROBINSON ALL-STEEL ELECTRIC TRUCK.

In the truck shown above, made by C. W. Robinson, of Altoona, Pa., the car body is supported at the extreme ends by springs—no less than a dozen of these springs being used in all. The yokes, in which the journal boxes ride, are made of continuous steel bars, braced below the journal box with an equalizing bar, which distributes the weight equally, and the car wheels and axles may be removed and replaced without disturbing the car body or brake mechanism, by simply removing a bolt at each end of the bars.

The brake can be applied from either end, all up to the wheels being gripped simultaneously. The brake bars slide on the rigid side frames and grip the wheels at the same point, regardless of the weight of load; the brake mechanism lies close up against the car body and does not interfere with the motor.

The motor or armature can be easily removed without disturbing the car body or brake mechanism, thus making all the electric parts readily accessible.

The construction is such that the truck is admirably adapted for the new gearless motor as well as for the old style motor.

MR. PAUL W. BOSSART, of The Short Electric Railway Company, is making an active and efficient canvass in street railway circles of the West. He reports the most favorable outlook for the new gearless motor. Everyone is interested in it and speaks in the highest terms of its simplicity, predicting a wonderful future for this new departure of the Short Company. Mr. Bossart is fortunate in representing so strong a company and one whose past reputation for reliability and excellence of work is of the very highest.

THE INTERIOR CONDUIT AND INSULATION CO.

One of the best proofs of the phenomenal success with which the Interior Conduit system is meeting is the number of large and costly buildings that are being erected in which the system is being used. We name a few of the buildings in which the Conduit system has been used throughout, or has been specified for by the architects:

Fair Building, Chicago, Sperry Electric Co., contractors; Henry Crocker, residence, San Francisco, Cal.; Mt. City Club House, Chattanooga, Tenn., S. C. Dodge, contractor; Phœnix Club House, Baltimore, Md., Southern Electric Co., contractors; Fourteenth Street Pumping Station, Chicago; the Greenwich Savings Bank, New York; Masonic Hall, Snug Harbor, Staten Island; Music Hall, Snug Harbor, Staten Island; Providence Trust Co., Providence, R. I.; Dr. D. B. St. John Roosa, residence, New York; the new building of the Metropolitan Telegraph & Telephone Co., Broad street, New York; Jackson Building, Union Square, New York; the Dunshee apartment house, Chicago; Jewish Temple, 5th ave. and 72d street, New York; and P. C. Hewitt's residence, No. 11 Lexington Ave., New York.

THE ENGINEERING EQUIPMENT CO.

Among all the new enterprises which have, within the last few months, been inaugurated in the electrical field, none have brighter promise of success than the Engineering Equipment Co., who have moved from their temporary quarters, at 73 Cortlandt street, to attractive offices in the fine new "Central Building," 143 Liberty street. They still retain the premises at 73 Cortlandt street for stock of belting, wires, etc., which they carry for convenience of customers who are not able to await shipments from the factories. It may be remembered that, as announced recently in these columns, Mr. Perine is general manager; Mr. A. L. Tinker, secretary and treasurer, and Mr. F. A. Magee, electrician, of the company. The others who are connected with the company devote themselves to the various branches of the business; and we understand that the success of this new company to date has been excellent, and the prospects are of the best. The company has been formed to handle the very best steam and electrical equipment materials, chiefly on large orders at close figures; and they are able invariably to quote as close as manufacturers on any goods that they handle.

Among the specialties which they control may be mentioned more particularly the following: The Underwood cotton-leather belts and belting specialties, in which they have a large and growing trade; the well-known and first-class Anderson line materials, including the Boston trolley for electric roads; the Habirshaw wires, cables and cores, the only line of wires recommended by the Government; the Patent indurated fibre pipe for electrical and other subways, which is by many considered to be the coming pipe and which is now greatly improved in manufacture; and the new Kellogg steel centre and side poles, for which the company are sole agents. Besides the foregoing they also handle the best boilers and engines, wooden poles, cross-arms, cars, trucks, etc.

It will be of interest to those who are in need of any of these materials to obtain a quotation from the Engineering Equipment Co.; and it is advised, if possible, that a call be made upon the gentlemen of the company at their new offices in the Central Building, where they will be very happy to meet the trade.

MR. C. F. BARNES has been appointed manager of the Indianapolis, Ind., telephone exchange.

WESTERN TRADE NOTES.

The Central Electric Company, Chicago, have come to the front with a new portable photometer, which seems to be especially appropriate now, when so much is being said about the efficiency of incandescent lamps. This machine will enable any station superintendent to measure the candle power of his lamps, and thus accurately determine exactly how much each lamp consumes. The instrument is being offered at a very moderate price, and promises to become popular at once.

Mr. C. E. Oldacre, the general agent of the Jenney Electric Motor Co., was in town recently for a few days. The Jenney Electric Motor Co. are now pushing their isolated, incandescent light business, and are now building some fine dynamos.

Mr. George B. Shaw, general manager of the National Electric Mfg. Co., of Eau Claire, Wis., was in town last week for a short visit.

Mr. A. D. Lundy, well and widely known in electrical circles, formerly chief engineer of the Sprague Equipment Co., and later chief engineer of the Southern District Edison General Electric Co., has formed a co-partnership with Mr. Frederick Sargent, the mechanical and electrical engineer, of Chicago. Mr. Lundy has been connected with the electric street railway business almost from its inception, and is one of the best posted men in this line in the country. They are located in handsome offices at 339 "The Rookery," Chicago, Ill.

Mr. G. A. Edward Kohler, Mr. Franklin W. Kohler and Mr. Thos. G. Grier will consolidate their interests on June 1st, under the name of Kohler Bros. & Grier. The firm will handle the well-known Eddy motors, heretofore sold by Mr. G. A. Edward Kohler. They will also be the sole selling agents for the U. S. for the Thwing Electric Co., of Chicago, manufacturers of the Gem incandescent lamps. In addition to this Mr. H. T. Paiste of Philadelphia, manufacturer of the Paiste switches and other specialties, has decided to open a Western office to facilitate the shipment and sale of his goods, with Kolher Bros. & Grier as managers. This branch of the business will be conducted under the name of H. T. Paiste. The firm contemplate adding to their line of specialties, as opportunities offer themselves, and as they are young men of ability and push, they have every reason to look forward to a successful career.

Mr. Thomas A. Edison visited Chicago last week. His trip was mainly in connection with the business of the local Edison Illuminating Co. here, but he also found time to look somewhat into matters electrical of the World's Fair, and expresses himself as highly pleased with the vigorous way in which Prof. Barrett is pushing forward the work. He is himself decidedly in favor of a united exhibit. He spent some time while here with Prof. Barrett and Mr. Frederick Sargent, the electrical engineer of the construction department, and was well pleased with the information these gentlemen furnished him with, and the active way they are working.

The Interior Conduit & Insulation Co. report through Mr. H. M. Underwood, their general Western agent, that the "Fair" building, now in process of construction, is to be thoroughly equipped with their conduit system.

The Electric Light Plant for the "Fair" building has been awarded, after a sharp competition among the representatives of the different companies, to the Sperry Electric Co., who will install a plant of 450 arc-light capacity, employing nine fifty-light machines to run these lamps. The Standard Electric Co., of Chicago, have obtained the contract for the incandescent lamps, which number 3,000 16 c. p. lights, and are operated by three 1,000 light machines. This company is building multipolar dynamos, which are giving universal satisfaction, by reason of their very perfect automatic regulation due to a special combination winding. The wiring will be done by the respective contractors for their systems. The deal was engineered through by Capt. C. F. Dunderdale, of the "Rookery" building, acting for the two fortunate companies. This installation will probably be the largest arc-light isolated plant in the country.

The Electrical Engineering Co. is one of Chicago's recent and prominent electrical organizations. The company have settled themselves in comfortable quarters at 603, Monon Building. The following gentlemen are the interested parties: Mr. E. M. Izard, well known in Western electrical circles as a member of the firm of Leonard & Izard, who, until their dissolution some time ago, was the general Western agent of the Edison Co.; Mr. R. H. Pierce, who was formerly the state agent of the Edison Co. for Wisconsin; Mr. R. E. Richardson, who, was associated with the Western Electric Co., in their lighting department, and Mr. G. W. Seymour. The company are carrying on the business of consulting and contracting electrical engineers, furnishing plans, specifications and estimates for the complete equipment, both power and electrical plant for electric light transmission and street railway equipment. They are agents for the dynamos of the Standard Electric Co. of Vermont, and the Perret motors, and general Western agents for the Clark wire. They are well backed financially and already receiving a large share of patronage, which augurs well for their future success.

NEW ENGLAND TRADE NOTES.

The Germania Electric Co. have removed their offices to Room 505, Exchange Building, 53 State street, Boston. Correspondence should be addressed, P. O. Box 3,068, Boston, Mass.

Mr. H. M. Nicholls has made the Redding Electric Company, of Boston, general selling agents, for New England, of the Star Electric specialties.

Mr. O. M. Johnston has connected himself with the Redding Electric Co., as traveling salesman. The Redding Co. are rapidly completing arrangements for vigorously pushing the sale of their goods, and there is already a brisk demand for their specialties.

The Shipman Engine Co., of Boston, have recently sold a 4 h. p. automatic engine to the Edison General Electric Co., for driving a dynamo in the Queen's County Alms House, Barnum's Islands, N. Y., and also a 4 h. p. engine to E. O. Hall & Sons, Honolulu, for driving a 40 light incandescent dynamo. These engines are fitted with boiler, with oil fuel, and automatically regulate the supply of fuel, so that the steam pressure is kept constant in proportion to the demand.

The Gould & Watson Co. are introducing another valuable article in the shape of a span wire insulator and turn buckle for use in electric railways. The insulator is illustrated and described in another column.

The Electric Gas Lighting Co. report business as extremely good this season. During April they did nearly three times as much as for a similar period last year. The demand for Samson batteries is unprecedented, orders coming in frequently for lots of 1,000. Col. Burnham is still in the far West, but he is expected home now about the first of June.

The New England Portelectric Co. gave a special exhibition this week of their system at Dorchester, to representatives of the Boston press. Mr. F. L. Pope, of New York, recently made an exhaustive report upon the practical working and possibilities of the system, and his estimates are extremely favorable. The Boston daily press are all loud in their praises of the progress made in the experimental track, a speed being now attainable of about 40 miles an hour. A full description of the experimental plant will be given in an early issue.

NEW YORK TRADE NOTES.

The Interior Conduit and Insulation Co., 43 and 44 Broad street, has issued an illustrated circular calling attention to the merits of its "twin conductor," recently described in these pages.

The C. & C. Electric Motor Co., 402 and 404 Greenwich street, have issued some timely literature relative to their fan motors and other outfits. They continue to do an enormous business in their fan equipments.

Stanley & Hall, 32 and 34 Frankfort street, have issued a very clever little circular anent their electric alarm, or "early morning call," which enables a man to sleep without worry as to being late, saves many a run for the train, and is a great promoter of peace and gaiety.

The Ball Engine Co., of Erie, Pa., E. T. Copeland & Co., agents, have issued some excellent campaign documents full of cold facts as to their engines for electric lighting.

The Thos. Murray Co., of 95 Liberty street, are putting in all the construction and equipments of the Rochester and Grand View Beach Railway. The Rae system is used. It is regular steam railway construction, and the cars will make 20 to 25 miles an hour. There will be 15 motor cars, and each will pull three trailers, if necessary. The road is to be ready by the end of this month.

Fort Wayne Plants.—The following sales have recently been made by the New York office of the Fort Wayne Electric Co.: 1,300 alternating incandescent lights, to the Asbury Park Electric Light and Power Co., Asbury Park, N. J.; 1,300 alternating incandescent lights, to the Richmond Light, Heat and Power Co., St. George, Staten Island, N. Y.; 650 alternating incandescent lights, to the Alumbrado Electrico de Barranquilla, United States of Colombia, South America.

The Eureka Tempered Copper Co., of North East, Pa., report large orders during the last thirty days from the Edison General Electric Co.; the Wenstrom Consolidated Dynamo and Motor Co.: Electro-Dynamic Co.; Wightman Electric Mfg. Co.; Thomson-Houston Electric Co.; Sperry Electric Mining and Machine Co.; Baxter Electric Motor Co.; C. & C. Electric Motor Co.; La Roche Electrical Works; McDonough Mfg. Co.; Shaw Electric Crane Co.; Thomson Electric Welding Co.; Colburn Electric Mfg. Co.; Ford & Washburn Electric Co., together with a large number of railroad bearings, and even with the dullness now prevailing in business circles, the demand for their tempered copper has constantly increased, instead of diminished.

THE
Electrical Engineer.

VOL. XI. MAY 27, 1891. No. 160.

THE JENKS POTENTIAL PROTECTOR.

THE "jumping" qualities of the electric current have been for many years relied upon as a means of securing immunity from damage to telegraph, telephone and other instruments which are subjected to occasional discharges of high potential. It was some time in the Forties that inventive genius was perhaps most active in this direction, and of the numerous forms of lightning arresters then put into practical use, Fig. 1, roughly outlines a good illustration. Here *a* and *b* are large plates supported on the roof of a telegraph office, so close together as to be connected by an atmospheric spark in case the difference of potential becomes too great, thus forming a shunt around the instruments in the building below, and even fusing together so as to maintain the circuit, in case the instruments burned out.

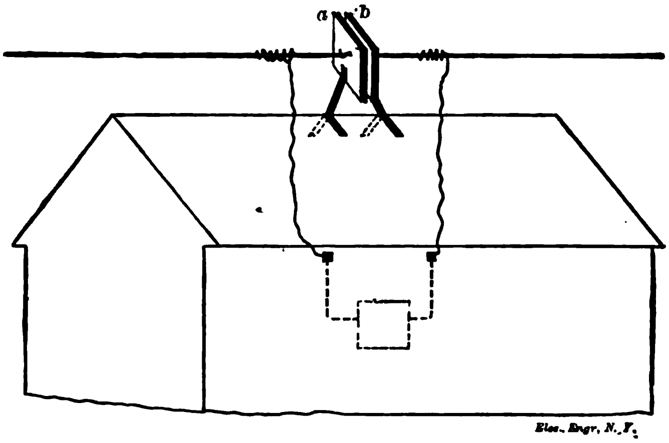


FIG. 1.—OLD FORM OF LIGHTNING ARRESTER.

Very early, also, films of paper were used to mechanically separate the plates, a dangerous pressure being sufficient to break down the fragile insulation and allow the plates to fuse together.

The application of these old cutouts to the protection of electric lamps, or the maintenance of the circuit in case of a rise of potential caused by the breaking of the lamp carbon, the failure of a feeding mechanism to operate, or a sudden rush of current from a lightning discharge or a short-circuit, did not probably involve invention. But the attempt to provide against very small variations of pressure, necessitated a delicacy of adjustment which none of the old forms possessed, and Fig. 2, illustrates how this delicacy may not only be secured, but maintained, by sealing or enclosing an air-space cutout or shunt so that it cannot be practically affected by dust or moisture.

It is a curious fact that the resistance of an air space, though practically immeasurable by any of our most delicate instruments, is overcome by a lower potential than an equal thickness of mica, paper or other mechanical insulator, which is so much better as a conductor as to be readily measured by an ordinary bridge.

This method of enclosing within an isolated cell, the air space which is to be relied upon to form the track of the current, is found by careful experiment to be absolutely essential in dealing with the low potentials from which delicate instruments must be protected, and the very close adjustment required to provide for a short-circuiting action with a predetermined potential may be secured by several methods. For the purposes of the Edison "municipal system" it is sufficient to bring the opposing conducting surfaces within about $\frac{3}{1000}$ inch of each other, while for other uses it may become necessary to narrow the space to about $\frac{1}{2000}$ inch.

Evidently adjustments as delicate as these can in practical work be made by the ordinary operative only by interposing between the electrodes a distance piece or washer of definite thickness, having one or more holes through which the discharge will occur, and this distance piece forms one of the most important points of the invention. It may consist either of mica, of perforated paper, silk bolting cloth or other suitable perforated film. By its means it is easy to set this potential cutout so that a rise of pressure from 150 to 200 volts, or even from 75 to 100 volts, will operate it with certainty, and cause the shunt to carry, either as a dead-short circuit or through a compensating resistance to the line beyond, or to ground, as the case may be, the normal current which might otherwise be broken, or the accidental current from some high pressure circuit, which might injure the instruments, and interfere with the circuit as a whole.

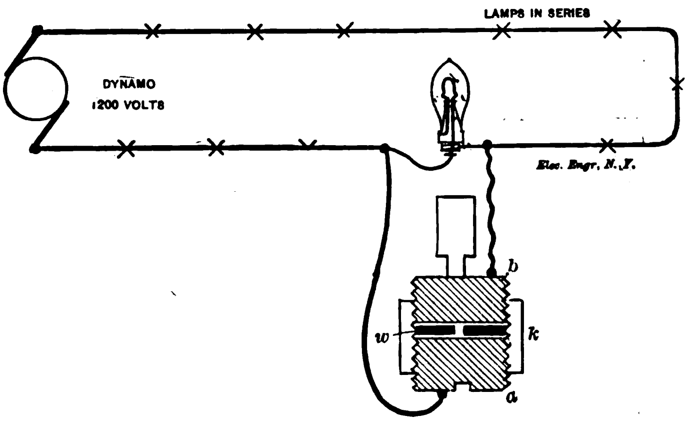

FIG. 2.—THE JENKS POTENTIAL PROTECTOR.

In Fig. 2, where the application to the "municipal" incandescent lamp is outlined, the size of the removable cell or button is exaggerated to show the construction. It consists simply of two metallic plugs *a* and *b* screwed into the threaded non-combustible moisture proof (lava) sleeve *k* against a washer *w* of mica, the space in the middle of the washer receiving the discharge. Several thousands of these have been used on Edison street lighting circuits for about three years. In February, 1890, the first test was made, by the New England Underwriters, of a combination of the air-space cutout and a circuit-opening device, as shown in Fig. 3, for the protection of telephone, district messenger, telegraph and other "innocuous" circuits, from the effects of crosses with their high pressure neighbors the arc, the alternating or the electric railway conductors, or from lightning. While many of the seventy-five forms of protectors then submitted for trial operated readily when a current flow followed a cross, the test demonstrated the absolute necessity of combining a fuse or magnet to open the circuit, with some device which would operate as this form does, namely, as the result of a rise in potential, without any current flow until a path is created by the protector.

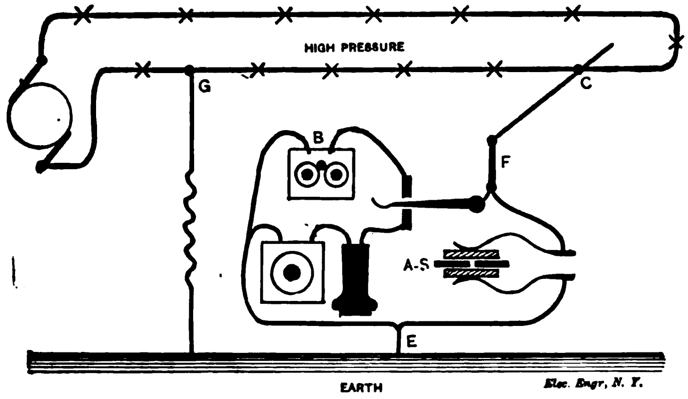

Fig. 3.—The Jenks Potential Protector.

Fig. 3, outlines a grounded telephone wire crossed with an arc, or other high pressure, circuit at the point C. If any leakage to earth from the arc circuit existed, as at G, a difference of potential will be set up between C and E, and a current will flow through the telephone or the bell B. If these be furnished with an air-space cutout A-S (forming a normally open shunt) and a fuse or electro-magnetic device F in the main circuit, the rise of potential will, if dangerous, cause a spark to jump from one plate to the other, reducing the resistance between the points C and E to a practical zero, and increasing the flow of current through the fuse so as to melt it and open the circuit before any harm can be done. Ordinarily this action will probably take place simultaneously at both ends of the line, and a telephone subscriber and the central station be alike protected.

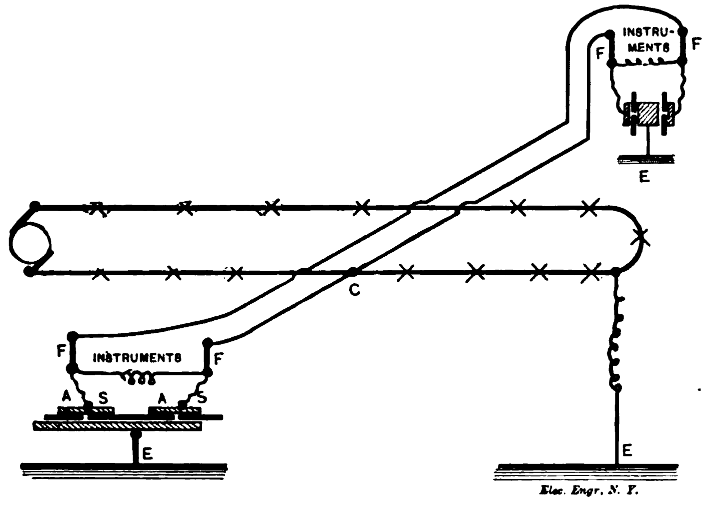

Fig. 4.—The Jenks Potential Protector.

Probably the most important application of this combination of potential and circuit opening devices will be to metallic circuits. Here it might be the case that absolutely no warning would be given of a cross of possibly dangerous character up to the moment that some one completed a path to earth by touching the telephone or the district messenger call box, or until leakage caused a fire. Fig. 4, shows the metallic circuit connections, and it is found that both wires at a given station will be instantly disconnected from the instruments when these conditions occur. This diagram also shows a very simple embodiment of the combination, a carbon strip being connected to earth and small carbon blocks to line, the separating medium being a perforated ribbon of mica. This is substantially the form which has within a year been introduced by the telephone companies, particularly in their long-distance work.

SIMPLE RULES FOR MEMORIZING ELECTRIC AND MAGNETIC ACTION.

BY

S. T. Moreland,

The purpose of this article is to give simple and easily remembered rules for determining, (1) the direction in which a magnetic needle will be deflected by a given electric current; (2) the direction of an electric current when the deflection of a magnetic needle is known; (3) the direction of the current produced in a conductor which cuts magnetic lines of force having a given direction. It is believed that the rules here given are simpler than those heretofore published. For understanding the rules the following assumptions must be borne in mind:—

1. That end of a freely suspended magnet which points north is called the north end of the magnet; by some called the north-seeking end.

2. The direction of a current of electricity is from carbon to zinc *outside* a cell composed of these elements.

3. The direction (sometimes called the *positive* direction) of a magnetic line of force, is the direction in which the north end of a magnetic needle points when placed on the line of force.

The rules, which will be explained and illustrated below, are as follows:—

Rule I. To find the deflection of a magnetic needle, grasp the current-carrying wire with the *right* hand, the outstretched thumb pointing in the direction of the electric current, then the fingers will go around the wire in the direction of the magnetic lines of force, and on whatever side of the wire a magnetic needle be placed its north end will be deflected in the direction in which the fingers go around the wire.

Rule II. To find the direction of a current, grasp the current-carrying wire with the *right* hand so that the fingers go around the wire in the direction in which the north end of a magnetic needle is deflected; the direction of the outstretched thumb is the direction of the current.

Rule III. To find the direction of the current produced when a conductor cuts magnetic lines of force, place the *right* hand with the fingers pointing in the direction of the lines of force and the palm so turned as to be struck by the moving conductor; then the outstretched thumb will give the direction of the current produced.

Rule I. may be verified by passing a current-carrying wire in a vertical direction through a horizontal platform on which a short magnetic needle, delicately pivoted, may be placed and its deflections observed. Suppose a current flowing up through the wire: Grasping the wire with the right hand, the thumb pointing up, the fingers will go around the wire in the direction in which the north end of the needle points. Apply the rule to the usual case of a wire in a horizontal position and lying in the magnetic meridian. Let the current flow from south to north, geographically speaking; then grasping the wire with the right hand, the outstretched thumb pointing north, we have the following cases :—

(*a*) *Above* the wire the fingers go towards the east; hence, if the needle be placed *above* the wire its north end will be deflected to the east.

(*b*) On the east side of the wire the fingers go *down;* hence, on that side the north end of the needle will go *down.*

(*c*) *Under* the wire the fingers go towards the west; hence, *under* the wire the north end of the needle will be deflected to the west.

(*d*) On the west side of the wire the fingers go *up;* hence on the west side of the wire the north end of the needle will be deflected *up.*

Rule II. may be verified by the vertical wire used to verify Rule I. As an example suppose a horizontal wire in the magnetic meridian carrying a current to be above a magnetic needle, and that we find the north end deflected to the east. To find the direction of the current, grasp the wire with the right hand in such manner that on the *under* side of the wire the fingers go towards the east; the outstretched thumb will be towards the south, and this will be the direction of the current. In the case of any coil of wire carrying a current, the direction in which the north end of the needle is deflected indicates the direction in which the lines of force pass through the coil, and if any part of the coil be grasped with the right hand so as to make the fingers pass through the coil in the direction of the lines of force, the outstretched thumb will point in the direction of the current.

Rule III. may be verified by means of a magnetic field where the direction of the lines of force are known, and a movable conductor forming part of a circuit including a suitable galvanometer. The rule is based on the very valuable suggestion, due to Mr. E. R. Carichoff, electrical engineer, that, just as a whip wraps around a rigid rod when it strikes one, so a line of force seems to wrap around any conductor which it strikes, and if we know the direction in which the lines wrap around the conductor we can tell the direction of the current by Rule II. Now the hand behaves just as the whip does; if we strike a rod with the palm of the hand (at right angles or nearly so to its length) the fingers will wrap around the rod, we have then only to put the right hand in the position of the lines of force, the fingers pointing in the direction of the lines and the palm turned so as to receive the moving conductor in order that the fingers may wrap around the conductor, the outstretched thumb will give the direction of the resulting current.

As an example, take a movable wire lying east and west and forming a part of a circuit, and suppose the wire moved *up.* The earth's lines of magnetic force go towards the north; the fingers of the right hand are therefore pointed north, and since the wire is to be moved up, the hand must be placed above the wire with the palm *down;* the outstretched thumb will then point west and this will be the direction of the current. If the wire be moved *down,* the fingers being towards the north, the hand being *below* the wire with the palm *up,* the thumb will point east and the direction of the current will be to the east.

It ought to be remarked that we do not suppose that a line of force which strikes a conductor actually wraps around it; on the contrary, we suppose the lines of force to cut across the conductor, *but the effect so far as the conductor is concerned is as if they wrapped around it.*

This use of the right hand is not the same as the use made of it by Prof. Jamieson in his excellent little books on Magnetism and Electricity, but the rules here given grew out of the reading of those books and the suggestion already mentioned, given me by Mr. Carichoff.

Mr. L. G. Hough, manager of the Indianapolis, Ind., Telephone Exchange, has resigned, and will take the agency of the Travelers Insurance Co., in that city.

RAIN CLOUDS AND LIGHTNING.

BY

Otis K. Stuart

In a recent article on "the Striking Distance of Alternating Electromotive Forces," Mr. Robert Shand, one of the ablest of the corps of assistants to Prof. Elihu Thomson, calls attention to a remark made by Prof. Thomson, concerning the electro-motive force of lightning discharges. Prof. Thomson has given considerable attention to the subject of auroras, lightning, and other atmospheric phenomena of an electrical nature, as was evidenced by his recent able lecture before the citizens of Swampscott, on the subject of thunder storms, and this remark is, therefore, worthy of more than passing consideration.

Mr. Shand states that he has heard Prof. Thomson remark (we suppose, during the course of conversation) that the "phenomenal values" of the electro-motive force, which are usually referred to in connection with lightning discharges, may be more fanciful than real. The electromotive force may break through one layer of the cloud and "act as a sort of electric wedge, capable of opening a path for itself, as it were, through many hundreds of feet." This suggestion is very curious as being in its way, confirmatory of Clerk Maxwell's idea as to the action of electro-motive forces through high resisting media. Clerk Maxwell, as Mr. Shand has said, likened this action to the splitting of wood by a wedge. First one layer of resistance is pierced by an electromotive force, then another layer, perhaps of less resistance than the first, then another and so on until, as in the case of wood, the whole resisting medium is pierced.

It is quite likely also that the conformation of the surface of a charged cloud may govern, to a large degree, the value of the electro-motive force of a lightning discharge. It has been noticed that after a flash of lightning there is frequently a sudden increased precipitation of rain. Even when a flash occurs during a violent down-pour, the precipitation immediately succeeding the flash is still more violent, and the rain drops are often larger than the average during the storm. If we suppose the cloud to project downwards from some part of its under surface, so that it presents a *point* to the earth's surface, it is clear that the cloud will be discharged from this point rather than from any other, not only because of the shorter distance between it and the earth, but also because the cloud does present this point. Gravitation acting upon the cloud would tend to accumulate the denser parts at its lower portions, and the projection thus formed would therefore serve as a comparatively good conductor to the passage of the electricity, which is another reason why the discharge would take place, with a moderate electro-motive force from this projection. Granting that the cloud behaves like a huge condenser consisting of successive layers of dielectric, the electro-motive force, piercing the interior or top layer of highest resistance, would find each succeeding layer in its downward path of lower and lower resistance, and its progress thus becoming easier and easier.

The characteristic phenomena of rain storms which are accompanied by lightning and thunder, are such that we may consider the rain clouds as huge, inverted, irregular cones, with the densest portions at the apexes. The centres of such storms are always the positions of greatest rain-fall, unless when affected by such disturbing influences as wind, temperature, etc. This volume of water precipitated decreases gradually from the center outward to the circumferential limits of the storm, where it is zero. There is generally a small area where the precipitation is very heavy, and all around this area there occurs a much lighter fall, the very lightest being at the storm's edge, which assumes the shape of an irregular circle.

The cloud thus acts as a wedge for entering the air between it and the earth. The striking distance is thereby decreased, there is a rough sort of point from which the discharge may readily take place, and the projection itself forms a comparatively good conductor to the passage of the electric current. If the projection were quite sharp (as might easily be the case, considering the dimensions of a cloud), and projected downward a considerable distance from the main body of the cloud, there might be a vivid discharge, of comparatively low electro-motive force and large current volume.

The same reasoning applies, though not with equal force, of course, to lightning discharges between cloud and cloud. Wind could readily cause a projection from one surface of a cloud toward another cloud. There would be a lessening of the distance between the too, and the formation of a projection, conical in shape, from the surface of one or both of them, and when the two clouds had approached each other close enough, the discharge, of comparatively low electro-motive force, would take place. If we consider the lighter portions of a cloud as driven more rapidly by the wind than the heavier, these latter, by lagging behind the former, would form such a projection, and in this case, the projection would be a comparatively good conductor of discharge current.

It is popularly supposed that the sudden down-pour of rain which generally at once follows a heavy lightning flash, is caused in some way by the flash itself. Of course, this is known not to be the case; and in view of the considerations above presented, it is quite possible that the sudden increased precipitation may be the real cause of the flash at that particular moment. By reducing the resistance through the striking distance, the increased precipitation offers a path for the discharge which, without this increased precipitation, it would be unable to follow; that is to say, the electro-motive force would not be high enough to pierce the dry air, but is high enough to follow the path of the multitude of large rain drops. Owing to the greater velocity of the light, we see the flash before we see the drops, but the latter really start on their journey before the former.

A PHOTOGRAPHIC STUDY OF THE ELECTRIC ARC, BASED UPON EXPERIMENTS MADE BY MR. J. C. McMYNN.[1]

BY PROF. EDWARD L. NICHOLS.

THE alternating current arc and the continuous current arc afford two entirely distinct fields of investigation. Candle-power, distribution of light, quality of light, temperature, efficiency, resistance, electromotive force necessary to maintain the arc, performance of the carbons under varying conditions; all of these are questions concerning which we have abundance of experimental data, so far as the continuous current arc is concerned. In the case of the alternating arc, however, these and many other points are still to be determined.

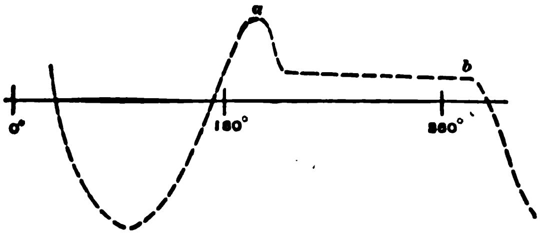

FIG. 1.—From Archbold and Teeple's thesis on the "Ball and Point" effect.

The arc lamp, fed by alternating currents, invariably hums and sings. The note, which is not to be mistaken for the hissing which we hear from continuous current lamps that are burning under improper conditions, possesses a definite pitch, determined by the rate of alternation of the dynamo. That the note is not due to the mechanism of the lamp itself is readily shown. The Jablochkoff candle, which is devoid of all mechanism, sings as merrily as the lamp with solenoid regulator; any form of hand-lamp will do the same. I do not remember having seen any definite statement concerning the source of this humming noise, nor any satisfactory discussion of the question. My attention was first brought to the very obvious explanation of the phenomenon by the study of certain curves of electromotive force, obtained by Messrs. Archbold & Teeple, in the course of an investigation of the alternating discharge between a ball and point.[2] These curves have recently been published. I produce one of them for the purpose of elucidation.[3] This curve was obtained by the well-known method of instantaneous contacts. The circuit under

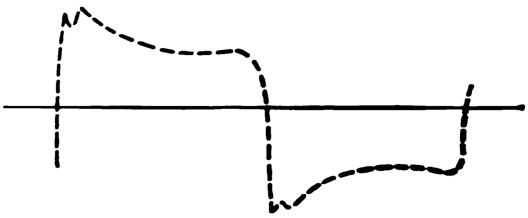

FIG. 2.—From Tobey & Walbridge's paper on the Stanley Arc Lighting Machine.

investigation was the high tension secondary of an induction coil, actuated by an alternating current dynamo, the E. M. F. of which followed the law of sines closely. In the circuit were placed a ball and point, the air space between them being such that the discharge would take place in one direction only, from ball to point. It was established, by the use of a revolving mirror, that an arc existed only during that part of each cycle represented by the horizontal portion of the curve. [*a*—*b*, Fig. 1.] Shortly after this curve had been obtained, the curves of Messrs. Tobey and Walbridge,[4] illustrating the performance of the Stanley arc

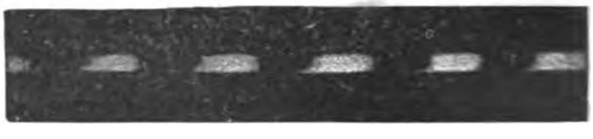

FIG. 3.—Alternating Arc. [Movement of plate horizontal.]

lighting dynamo, appeared. It will be remembered by those who heard their paper read before the Institute, that this machine, which gave very nearly the sine curve of E. M. F. when working through non-inductive resistance, showed curves very widely removed from that form when arc lamps were in the outer circuit.

Fig. 2 contains the curve of the arc-lighting machine when five lamps were in circuit. The relation of this curve to those obtained with the ball and point is evident. Here, also, the variation of the curve from sinusoidal form is to be ascribed to the periodic formation and breaking down of the arc, which happens twice in every complete cycle, instead of once, as in the case of the "one way" discharge of the ball and point phenomenon.

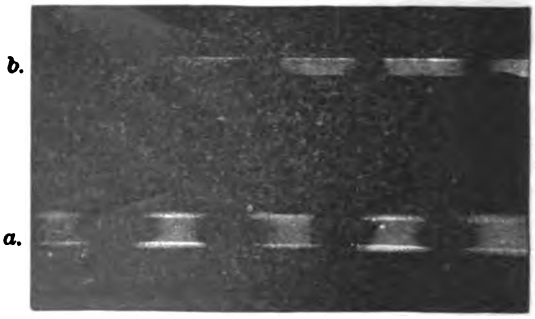

FIG. 4.—Alternating arc. *a*. Long arc (58 volts). *b*. Short arc (43 volts). [Movement of plate horizontal.]

After studying these curves it seemed to me unquestionable that the humming of the alternating arc is due to the rapid periodic extinction and re-establishment of the discharge, the effect being similar to that observed in singing flames. When, some months later, opportunity was found of viewing the image of the arc of an alternating current lamp in the revolving mirror, I was prepared to witness the extinction of the arc during a definite part of each alternation.

[4] Tobey and Walbridge; TRANSACTIONS, Am. Inst. Elec. Eng., Vol. 7, p. 367

Mr. McMynn's first step in the investigation was to photograph the arc under conditions which would bring out this phenomenon.

These photographs establish the intermittent character of the alternating arc beyond question. They also exhibit in a new light many interesting properties of the arc, some of which are already well-known, while others have not been noted. Of the many negatives already obtained, a few characteristic forms are given in the accompanying plates.

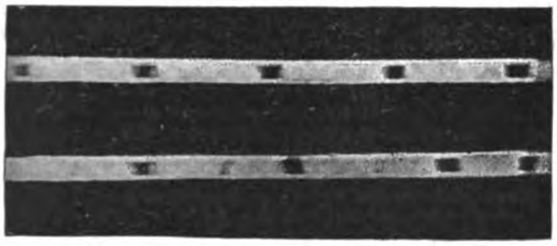

FIG. 5.—Alternating arc. [Movement of plate horizontal.]

Figs. 3, 4, 5 and 6 show the results obtained with plates moving in a horizontal direction, at right angles with the axis of the carbons of the lamp. Fig. 3 is an enlargement of one of the first negatives taken. The speed of the plate was moderate, the size of the image smaller than the arc itself. The plate contains but little detail. The carbons do not appear at all in the photograph, which shows little besides the periodic interruption of the arc. Inspection of Figs. 4, 5 and 6 shows that the greatest intensity resides neither in the arc itself nor on the incandescent carbons, but in a narrow region just at the ends of the arc. In this region, which, doubtless, is that where the so-called "contact resistance" of the arc occurs, the illumination is sometimes intermittent, as in Fig. 4; sometimes nearly uniform, as in Figs. 5 and 6. The relative width of the intervals of darkness and of light is also seen to vary greatly under conditions not yet determined. Fig. 6 represents the highest rate of speed given to the plate in any of these exposures. The image of a single alternation was in this case extended almost across the plate. No new features were brought to light, however, by this process of magnification.

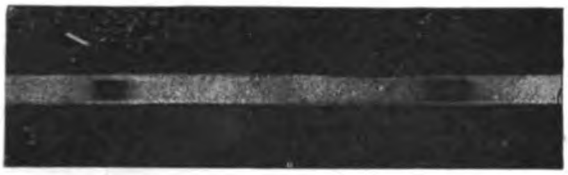

FIG. 6.—Alternating arc. [Movement of plate horizontal.] High speed.

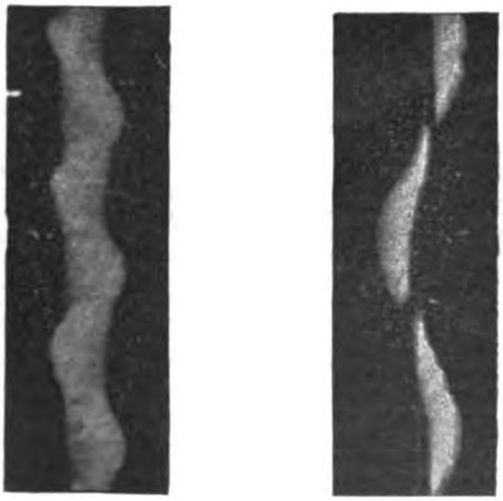

FIG. 7.—Alternating arc. [Movement of plate vertical]. *a.* Showing oscillations due to earth's field. *b.* Showing oscillations in a stronger field.

Figs. 7, 8, 9, 10, 11 and 12 were obtained by driving the plate vertically through the field, parallel to the carbons. An unlooked-for feature of all these plates was the oscillation of the arc from right to left in synchronism with the alternation period. Mr. McMynn suspected this vibration to be due to the action of the earth's magnetic field.[5] He was able to verify his view by comparing photographs made with the camera placed with its optical axis in the meridian with others in which the arc was viewed from the east or west. The disturbance was most marked in the former position and disappeared almost entirely from negatives taken in the latter. This point is well illustrated by Fig. 8 (*a* and *b*), which shows the image obtained from the north and from the east. The lamp in this case was supplied with cylindrical carbons. All the other photographs represent the arc between flat carbons. In a strong field produced by placing the arc nearly between the poles of a horse-shoe magnet, the lines of force being perpendicular to the axis of the lamp and parallel to that of the camera, the vibratory effect was much increased. [See Fig. 7 (B).] The bearded appearance of the arc in Figs. 9, 10 and 11 is common to all the negatives taken while the arc was in the strong field. The spines are supposed to be the paths of very minute and highly incandescent particles, expelled from the arc at a considerable velocity under the action of the magnetic forces. A continuous cur-

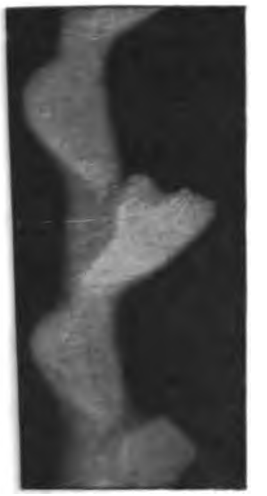
FIG. 10.—Alternating arc. [Movement of plate vertical; arc in strong magnetic field.]

---

[5] It should be noted that Casselmann, as long ago as 1844, described the deflecting action of the earth's field upon the continuous current arc. (See *Poggendorff's Annalen*, 63, p. 588.)

rent arc, also in a strong field, the conditions being as nearly as possible those under which Figs. 9, 10 and 11 were taken, gave a negative of which Fig. 12 is a very imperfect representation. The arc was flaming, and it will be seen that while the path of the arc itself is an unbroken, straight trace, the flames, which show themselves to the right and left hands, are irregularly intermittent. The negative shows, moreover, that the flame to the right hand, in the figure, is finely striated, reminding one of the image of a hissing, sensitive gas flame, as the latter appears in the revolving mirror. This vibration, which must represent a pitch of several thousand vibrations per second, is, in all probability, the cause of the hissing of the arc.



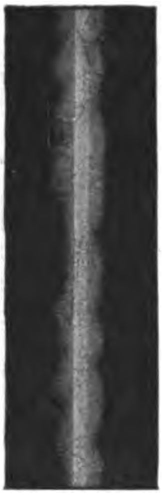


FIG. 11.—Alternating arc. [Movement of plate vertical; arc in a strong magnetic field.]
FIG. 12.—Continuous current arc. [Movement of plate vertical; arc in strong magnetic field; arc flaming.]

In this brief discussion I have left untouched many points which will suggest themselves to those who study Mr. McMynn's photographs. The interpretation of many of the features of these plates is at present rather obscure, but it is hoped that experiments now in progress will add something to our present knowledge of the phenomena connected with the alternating electric arc.

THE PERFECTION OF STATIONARY ELECTRIC MOTORS.[1]

BY FRANCIS B. CROCKER.

A STUDY of the history of the electric motor shows us that from the very beginning to the present time there has been a great tendency toward complicated, fanciful and unpractical designs, including outlandish forms of field magnets and unnecessary multiplicity of field cores and coils. In most cases also the mechanical construction has been very bad, the shaft being too small, the bearings being weakly supported, and the general finish and workmanship being rough and not up to the standard of first-class machinery. From the electrical standpoint the insulation has been very poor, and shares equally with imperfect mechanical construction, the responsibility for the numerous troubles and failures which have occurred with electric motors.

Electric motors are used for three different classes of work. First, transmission of power over considerable distances, for example from Niagara Falls to Buffalo; second, distribution of power, for example in a district of a city from a central station, and third, electric railway work.

The first of these classes of work usually requires large motors, over 50 or 100 h. p.; the second requires comparatively small motors, ranging between 1-8 and 10 h. p.; the third requires motors from 20 to 100 h. p. and a peculiar construction adapted to their special purpose. I purpose to consider in this paper motors of the second class for distribution of power especially.

It has long been my opinion that the proper way to design a good electric motor is to consider very carefully and systematically each part, first by itself, and then with reference to the other parts, and thus collect and build up the elements which are best, not only in themselves, but also in combination with each other, so that finally by putting and fitting these parts together with the best possible workmanship, the best result will certainly be obtained. Let us now take up the various parts of the electric motor, and consider each as a simple problem in designing.

The base should be a solid iron casting, flat and simple in form, and resting directly and squarely upon the base frame or floor, which latter should preferably be of wood to secure insulation. The base should be heavy to bring the centre of gravity low; in fact, this is the only part of the machine where weight is not only not objectionable, but very beneficial, and, since it is merely of plain cast-iron, the extra cost is insignificant. A heavy base does more than anything else to give great stability and strength to the whole machine, and is highly desirable in a stationary motor. The bearings should be directly and rigidly mounted upon this base, a simple fact that is often disregarded.

The field magnet should be *bipolar* except in the larger machines, above 10 h. p., on account of the great complication caused by the increased number of armature sections, commutator bars, field coils, etc., necessary in multipolar machines, and the narrowness of the neutral or non-sparking space on their commutators. The field should also be of the single magnetic circuit rather than the consequent pole type, because the former is more economical in wire and current required. A single circuit requires only 70 per cent. of the weight of wire, and 70 per cent. of the energy of magnetization that is required by a double magnetic circuit. A triple magnetic circuit or quadruple magnetic circuit is still more objectionable, requiring about twice as much wire as a single core of the same total cross-section.

The field magnet may be arranged with respect to the base described above in three general ways: First, the pole pieces may be set upon the base (Edison type); this form requires non-magnetic material, usually a zinc plate, to be interposed to prevent magnetic short-circuiting through the iron of the base; even with a zinc plate Hopkinson found 10.8 per cent. magnetic leakage through the base of the Edison-Hopkinson dynamo.

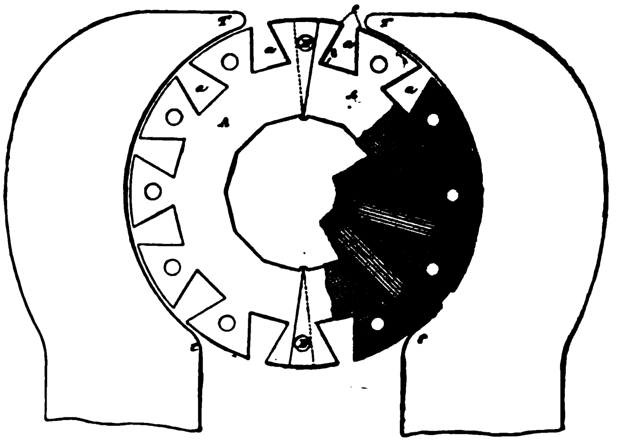

FIG. 1.—ARMATURE OF CROCKER-WHEELER MOTOR.

Second, the iron base may form one of the pole pieces (Manchester type). This is also objectionable on account of the greatly increased magnetic leakage, which is practically proportional to the surface exposed to the air, and the extension of the base necessary for the bearings, etc., greatly increases this surface, and also allows the magnetism to leak up into the shaft, pulley, etc., causing various troubles. This form has the further objection that it is of the consequent pole type, the disadvantage of which I have just pointed out.

Third, the iron base may form the yoke of the field magnet with the cores and pole pieces extending upward (Kapp or "inverted horseshoe" type). This plan has neither the leakage nor other faults of the other forms and possesses the great advantage that the pole pieces are removed as far as possible from the base, bearings, etc., thereby avoiding magnetic leakage; and the base being purposely made heavy for stability and strength, as already stated, is therefore exactly suited to being used as the yoke, thus performing two functions to the best advantage. There is, moreover, no objection to using a cast-iron base as the yoke to complete the magnetic circuit, since the heavy base I have insisted upon is of large cross-section, and therefore of ample magnetic permeance, and the increased size of the iron yoke does not aggravate the magnetic leakage because it is magnetically neutral. The field cores should be of wrought-iron, because the field wire surrounds them, and the use of cast-iron, which is of low permeability, would require a core of almost twice the cross-section, and therefore a much greater length of wire to obtain the necessary magnetizing force. With the smaller wrought cores the magnetic leakage would also be less. The pole pieces should also be wrought iron to reduce their size, and therefore their magnetic leakage, they being at the highest magnetic potential of any part of the machine. Magnetic leakage is objectionable, not only on account of wasting lines of force, but because it affects electrical instruments, watches, etc., in a very troublesome manner.

---

[1] Abstract of a paper read at the General Meeting of the American Institute of Electrical Engineers, New York, May 20th, 1891.

The field magnet cores and pole pieces being preferably of wrought-iron, the question of uniting them to the base and to each other next arises. Since any considerable fitting or working of wrought-iron is difficult and costly, the best solution of this problem certainly seems to be to drop-forge the core and pole piece in one piece. This also permits the bore or space for the armature to be perfectly formed at the same time. In connecting these cores to the cast-iron base, it is practically essential to set them into it in order to get sufficient contact and strength; since the ordinary butt joint between wrought and cast-iron limits the magnetic conductivity almost as much as if cast-iron were used throughout. This method of putting the magnetic circuit together reduces the work of fitting wrought-iron to a minimum, which work is the only objection to the use of wrought-iron. The supposition that cast-iron is cheaper than wrought for magnets is a fallacy, as its permeability is as much below that of wrought iron as is its price, both being about one-half.

The field coils should of course be perfectly insulated, a result which can be accomplished with certainty by winding them on a solid spool of material which is fire and water proof and highly insulating. These spools should never be made of material that softens by accidental heating of the wire, as this would allow the wire to cut through and make a "ground" on the core, which is just what the spool should prevent. I have tested spools of this kind which cut like cheese when a wire heated by a current was applied to them, this being a very effective method of testing this point.

In regard to the choice between the ring and drum forms of armature, the advantage of the drum is that it is easy to support mechanically, but it is difficult to wind, and more serious than anything else is the fact that the wires of a great difference of potential cross or approach very near each other, causing great liability to short circuit. The ring armature is somewhat hard to support mechnically, but the winding does not tend to slip out of place or pile out on the ends, and wires of the greatest difference of potential come at the greatest distance apart; that is, on opposite sides of the armature. This is of the utmost importance in the case of high voltage machines. In the case of large ring armatures, or those with few turns of wire, there is little trouble in winding; but in the case of the small ring armatures, or where a great number of turns of wire are used, the ring should be split in halves to facilitate winding, and put together afterward when wound.

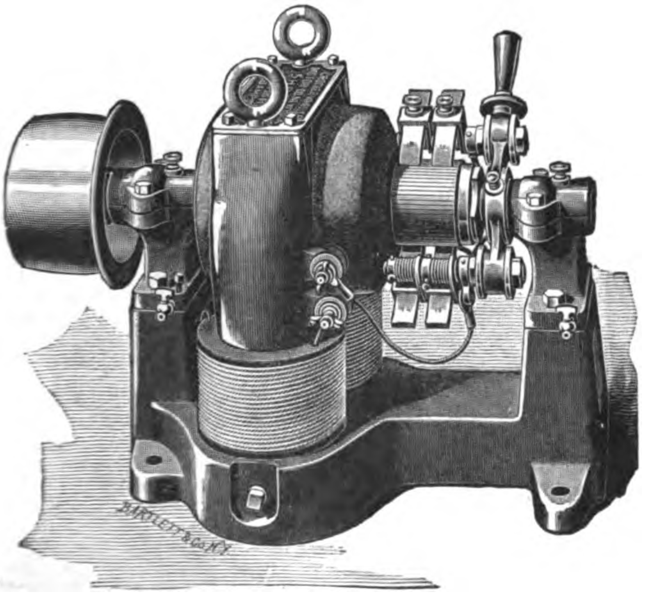

FIG. 2.—CROCKER-WHEELER MOTOR.

The armature should have teeth or projections upon it in order to secure the following advantages:

First, to reduce the reluctance of the magnetic circuit and the weight of wire and energy of current required to magnetize it. Second, to hold the wires in place and prevent them slipping tangentially on the core, there being a tangential pull of about 160 lbs. on the wires of a 10 h. p. armature 8 in. in diameter running at 1,000 R. P. M. Third, the teeth protect the wires from mechanical injury, since any blow or pressure which the armature receives comes upon them instead of upon the armature wire.

In the trapezoidal tooth armature, the teeth are considerably wider at the top than at the bottom, which of course makes between the teeth a slot which is wider at the bottom than at the top. This shape of tooth and slot has the following advantages over those of the ordinary toothed armature: Frst, the wire is more completely held in place, being held against centrifugal force as well as against tangential force; second, the wire is also more perfectly protected mechanically since it is almost entirely surrounded by iron; and third, the armature presents an almost unbroken magnetic surface to the pole pieces, thereby reducing to a minimum the reluctance of the air-spaces in the magnetic circuit and the magnetic leakage, and avoiding Foucault currents and loss of energy in the pole pieces. This trapezoidal form of slots and teeth can be still further taken advantage of by giving the former a shape which exactly agrees with the form of a section of winding on the inside of a ring, as shown in Fig. 1, the interior spaces for winding being divided into the necessary number of sections by radial lines. This exact conformity between the inside and outside of the winding makes a perfectly symmetrical coil, with no tendency for a single turn of the wires to cross at any point, and the coils on the inside occupy the whole space with the greatest possible advantage, whereas ordinarily the interior of the ring is liable to be overcrowded with wires. The trapezoidal form of slot is particularily economical as regards winding, for the reason that there are a greater number of turns in the inner layers which are shorter, and fewer turns in the outer layers, which are longer, as shown in Fig. 1. The armature teeth make it easy to support the ring perfectly, since the bolts for carrying it may pass through the teeth without interfering with the winding. The perfect insulation of the armature core is of the utmost importance. The best material and the most complete covering should be used, and the greatest possible care should be exercised to avoid short-circuits, "grounds," or broken wires.

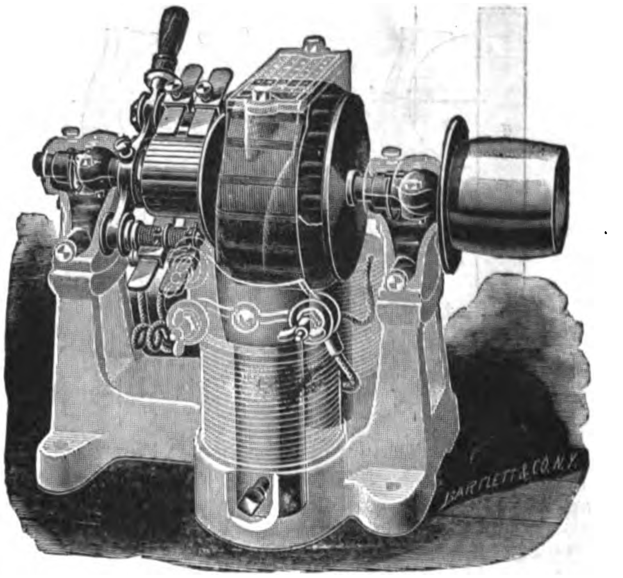

FIG. 3.—CROCKER-WHEELER MOTOR.

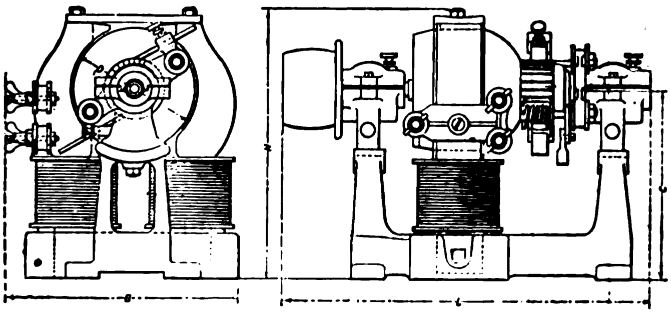

DIAGRAM SHOWING DIMENSIONS OF CROCKER-WHEELER MOTORS.
(*See Table.*)

The efficiency should, of course, be as high as possible, and is made a maximum by reducing all elements of loss as far as possible. These losses are, current to magnetize field, loss due to armature resistance, friction, resistance of air, Foucault currents, and hysteresis. It has always seemed to me that if a machine can be run for one or two hours at full load without any part becoming overheated, the efficiency of that machine must be high, unless the machine is very large and heavy for its power, in which case the surface for radiation and conduction would be great. This fact is more absolute than any efficiency test can possibly be, and very small losses which an efficiency test might not disclose would be indicated by local heating, if, for example, the effects are allowed to accumulate for a half hour of steady running.

I can best illustrate the foregoing statements and recommendations by describing the set of electric motors designed by Dr. S. S. Wheeler and myself. They were developed by precisely the same process of reasoning as that given in this paper.

Fig. 3 shows the general view of the motor; the fields are put together according to a method, illustrated in Fig. 4, which consists in drop-forging the core and pole piece in one piece and exactly to shape; then mounting it upon a holder in such a way that the ends of the cores are trimmed with exact reference to the armature bore; and holes being bored in the cast-iron base the proper distance apart, the cores are set into it to the depth they are trimmed off and produce a space for the armature exactly suited to it. The field cores set into the base are shown in the skeleton drawing, Fig. 3.

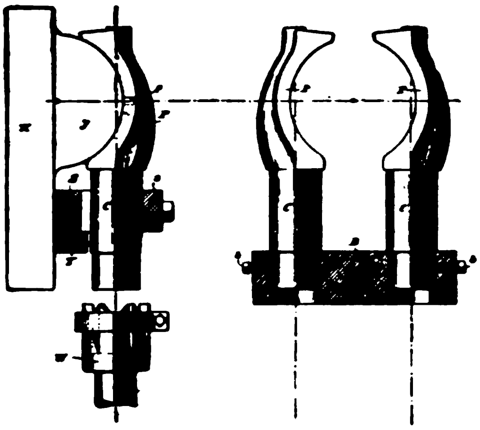

Fig. 4.—Method of Assembling Fields.

The magnetic circuit produced by this method is excellent. In the first place, there are only two joints and these are of very large surface and fit perfectly, being where the cores fit into the base. The surface of contact of each of these joints is about four times the cross section of the core, and therefore about twice the cross-section of the equivalent cast-iron. The core and pole piece being made integral, avoids any joint between them as well as any necessity for expensive work in fitting them together. In fact, the only machine work required in fitting the fields to the base is simply trimming off superficially the ends of the cores and reaming the two holes in the cast-iron base, these holes being cored out in the casting.

The armature is made with trapezoidal teeth, as shown in Fig. 1, and having an almost unbroken surface of large extent exposed to the pole piece with a clearance of only one-sixteenth of an inch, the magnetic reluctance of the air gap is reduced to the lowest possible value. This reduces the amount of wire required to excite the field to such an extent that only very short field coils and cores are needed, being only about one-third or one-quarter of the length required with armatures having no teeth and the ordinary air gaps in the magnetic circuit. This small quantity of wire on the field, amounts to only 12 pounds in a three h. p. machine and 16 pounds in a five h. p. machine. It has not only the advantage in economy of wire, but also makes the machine very efficient as regards current consumed in the field, being less than two per cent. in the two machines referred to. The reduction of field wire and length of coil required, is particularly important in bringing the shaft of the machine down sufficiently near the floor to give the machine stability and steadiness in running. In the type of motor described, the shaft centre is less than a foot from the floor in the three h. p. size, and is just about the proper height to make the pulley, belt, gear wheels or other mechanical connections clear the floor and have sufficient room to work properly. This complete overcoming of the heretofore serious objection to the "inverted horseshoe" type makes a thoroughly satisfactory field construction without any of the disadvantages of all the other forms.

The actual results obtained from these motors are given in the following table and include the various mechanical, electrical and magnetic constants of the machine. All the sizes of this type of motor are made almost exactly the same in design, proportions and construction and differ only in scale, hence a description of one machine applies to all, with proper allowance for difference in size.

Data of three h. p. Crocker-Wheeler motor, designed for 115 volt constant potential circuit:

Total weight	350	lbs.
Weight of field wire (No. 24 A. W. G.)	12	lbs.
Weight of armature wire (No. 13, A. W. G.)	11	lbs.
Resistance of field	810	ohms.
Resistance of armature	.4	ohm.
E. M. F. of circuit	115.	volts.
Total current at full load	24.3	amps.
Current used to excite field	.37	amp.
Percentage of current used in field	.015	
Total current required to run free	1.9	amp.
Percentage of total energy to run free	.08	
Commercial efficiency	.80	
Armature speed	975.	r. p. m.
Total magnetic leakage or waste lines of force	.17	

$$\text{Magnetic efficiency} = \frac{\text{Lines through armature}}{\text{Total lines of force}} \ldots\ldots .83$$

The above data for the most part explain themselves, but I desire to call attention to several particularly interesting points.

The weight of field wire is extremely small, being only 12 lbs., compared with about 40 to 50 lbs. in most machines of this size. I actually found the weight of field wire to be 60 lbs. in a type of motor of equal capacity, which is claimed to have the best possible magnetic circuit.

The table also shows the current used in field to be only 1½ per cent., which is remarkably low for machines of this size, which usually require about five per cent.

The current required to run free, at full speed, is also exceptionally small, being only eight per cent.

The commercial efficiency is high for a motor of this size, particularly when the very low speed is considered, because an increased number of turns of wire on the armature is required to make up for the reduced speed, and this augments the armature resistance and causes loss. The efficiency does not vary more than about one per cent. from half to full load, which is quite an interesting fact.

The speed, it will be noticed, is very low for this size of machine.

The magnetic leakage or loss of lines of force is extraordinarily small, amounting to only 17 per cent., and giving what may be properly called a magnetic efficiency of 83 per cent.

This small magnetic leakage is due to the design of the field magnets. In this connection it should be remembered that Hopkinson, in his classical investigations of the magnetic circuit, found that there was 24.94 per cent. magnetic leakage in the Edison-Hopkinson machine. I may also state that Mr. A. S. Ives, student in Electrical Engineering at Columbia College, found 40 per cent. leakage in a well-known 400 light dynamo of a recent, though not the very latest, type.

In conclusion, I would state that it is obviously impossible, in one paper of reasonable length, to completely treat the subject of motor design, but I have attempted to bring out the most important points, and lay before the Institute the best results of considerable study and experimental work on the part of Dr. Wheeler and myself in the direction of improving and perfecting the design and construction of stationary electric motors.

The ideas I have advanced are embodied in a large number of actual working machines which are open to anyone for examination and criticism.

THE COPPER PRODUCTION OF THE WORLD.

Messrs. Merton's annual statistics of the copper production of the world show that the output of 1890 reaches the highest figures yet attained. The production of the United States has more than doubled since 1883, and last year's output was upwards of five times that of 1879.

TESLA'S EXPERIMENTS WITH ALTERNATING CURRENTS OF HIGH FREQUENCY.

THE Wednesday evening session of the American Institute of Electrical Engineers was held in Prof. Dwight's room, Columbia College, and will long be remembered by those present, not only on account of the brilliant experiments shown, but also for the many possibilities which it suggested in the development of the artificial illumination of the future. For the purpose of his experiments, Mr. Tesla employed the alternating machine with 384 poles, described in THE ELECTRICAL ENGINEER of March 18, 1891, which, when run at full speed, permitted him to obtain 20,000 alternations per second. The currents of this machine in all of Mr. Tesla's experiments were first run through a condenser in order to avoid the possibility of injury to the machine. The machine itself was set up in the electrical workshop of the college and was driven by an electric motor, the speed of which could be varied by a switch on the lecture platform.

Mr. Tesla introduced his subject by the remark that modern science has been able to make rapid strides by the recognition of ether as the medium of transmission of vibrations of various forms which manifest themselves to our senses. We are therefore now able to see things in a different light than was formerly the case, and, being tolerably well able to explain them, the truth cannot be hidden much longer. The answer to the question, "What is Electricity?" we were not yet prepared to give. We were justified in assuming, however, that electric phenomena are ether phenomena, and we may consider the phenomena of static electricity as phenomena of ether under strain, and those of dynamic electricity and electro-magnetism as phenomena of ether in motion.

Mr. Tesla, while expressing the highest consideration for the work of Dr. Lodge, was not in entire accord with the views advanced by him, which he considered to be more of the nature of ingenious explanations than of a probable theory, Mr. Tesla contending that there can be no two electricities.

Alluding further to the electro-magnetic theory of light, and to the Hertz experiments and those of Dr. Lodge and their application to the production of an efficient source of light, Mr. Tesla considered the electro-magnetic waves as unavailable for the production of luminous effects, for the reason that long before we could reach the necessary frequency the conductor would become opaque to the passage of the waves. Mr. Tesla thought that electro-magnetic waves, unless they have the frequency of true light waves, cannot produce luminous effects, Not so, however, with the electrostatic waves or thrusts. These, no matter what their frequency, can excite luminous radiation. He reasoned that the static effects in the Hertz and Lodge experiments were excessively small, due to the fact that they were produced in a practically closed coil, the spark acting as a bridge, making the coil practically continuous and depressing the potential. To obtain the desired difference of potential we must work with an open circuit generator of high potential of high frequency to enhance the electrostatic effects, and it was the recognition of this fact which led Mr. Tesla to the results he showed.

In carrying out this idea of obtaining enormous differences of potential, Mr. Tesla at once encountered the difficulty of obtaining the requisite insulation for the induction coil employed by him. His experience demonstrated that what we consider the best insulators, such as glass and rubber are inferior to others, not formerly so considered, such as oil and wax. Mr. Tesla then started a spark coil in action, the primary of which was in connection with his alternator which was speeded to give from 10,000 to 11,000 alternations per second. The coil emitted a clear note, which rose as the number of alternations was increased. As the discharges took place between the terminals of the coil, an exhausted Geissler tube held in proximity to the discharge did not light, but upon blowing out the arc the tube lighted up, which was due to the rise of potential caused by the rupture of the arc. This effect Mr. Tesla considered as purely electrostatic.

Mr. Tesla then showed the influence of insulated bodies having considerable size upon the spark length, demonstrating the effect of capacity upon the nature of the discharge. Thus when we attach an insulated body to the terminal of the coil, the potential may be raised or lowered. He showed this by wrapping an insulated wire of about one foot in length about one terminal of the coil, and touching the other terminal with a brass sphere held in the hand; under these conditions streams of light emanated from all sides of the wire. When the sphere was removed, however, the streams disappeared almost entirely. He then cut off the wire in successive lengths, and the stream discharges became more marked and brilliant. He then attached a fine platinum wire to the terminal, which also showed the streams to a remarkable degree, and kept up a continuous vibration to and fro. He also showed a pinwheel effect, the wheel being rapidly rotated with streams issuing from the two points. Another experiment consisted in attaching two spheres of about four inches diameter to the terminals. The spark passes first between the two points nearest to each other on the spheres, then works up toward their tops, is extinguished and is re-established at the first point, this being continuously repeated. The neighboring exhausted tubes and lamps were illuminated and extinguished in unison with the action of the spark between the spheres. These Mr. Tesla pointed out were not electro-magnetic vibrations like the Hertz waves. He showed how by the use of the dielectric the spark is induced to jump between the separated spheres, due to the increase in the specific inductive capacity of the medium, and he also demonstrated that the streaming discharge passed easily through thick glass plates, rubber plates and a book. Mr. Tesla then showed these static effects in a non-striking vacuum. A tube of this nature when connected to the machine glowed brightly, and the terminals became incandescent. Mr. Tesla then remarked that if, instead of using a filament in a lamp—which necessarily limited us in the degree of incandescence which we could practically employ,—we could employ solid blocks of carbon, much higher efficiency could be obtained. Based upon this reasoning, he had constructed a lamp which he showed, containing two blocks of carbon in a non-striking vacuum. When connecting these two carbons to the two terminals of the coil or one to one terminal and the other to a body of some size, the blocks can be raised to high incandescence.

Mr. Tesla also showed a lamp with but a single rod filament in a non-striking vacuum with no outward connection. The energy is entirely transferred by condenser action through the medium of condenser coatings in the base of the lamp. He also pointed out how the brilliancy of the lamp could be varied by simply altering the relative positions of the condenser coatings. This Mr. Tesla followed by demonstration of the phenomena with an unexhausted globe, and a single filament mounted therein. The filament when connected to one terminal of the coil heats up to bright incandescence and spins around in the globe. He also demonstrated the heating by the use of Crookes' well-known apparatus consisting of mica vanes mounted above a platinum wire, which was brought to incandescence by connection with one terminal of the coil, and rotated the mica vanes.

In order to still further verify the conclusions that the electrostatic effects are alone active, Mr. Tesla placed a Geissler tube at right angles to the coil and at its centre. In this position the tube did not light up. When placed at the ends, however, the tube lit up brilliantly and gave sufficient light to read by. Mr. Tesla showed both uranium and yttria tubes.

He then showed how exhausted tubes could be made to glow in an electrostatic field. For this purpose two large sheets of zinc were connected to the terminals of the machine at a distance of about 15 feet apart. The tube when placed between these sheets glowed brilliantly and could be moved about freely. Mr. Tesla remarked that, by merely creating such a field in a room, the mere suspension of the tubes in the room would afford the desired illumination.

Coming to the physiological effects, Mr. Tesla adjusted the conditions so that by touching one terminal with a brass sphere he raised the potential of the coil so enormously that a stream of light came out on the other terminal, and he estimated the difference of potential to be nearly 250,000 volts, and then performed the remarkable experiment of receiving the total discharge through his body, protecting his hands from burning by the brass balls held in his hands.

He then lit up lamps by holding them in contact with one terminal or near to the coil.

The lecturer then came to another class of experiments. He stated that he had used a system of conversion from high tension to low with the enormous frequencies of the condenser discharges. Mr. Tesla then showed an interesting experiment which consisted in passing the converted currents, produced in the manner just described, through a copper bar [illegible] inch in diameter and bent into a loop. Ordinarily such a bar would constitute a short circuit, but Mr. Tesla succeeded in bringing lamps stretched across the parallel sides of the bar to incandescence, demonstrating that the impedance in the loop connecting the two sides was so great as to practically prevent the current from passing through it and hence acting upon the lamps in the manner described. He also pointed out the existence of modes on the bar. His method consists in continuously charging and disruptively discharging a condenser into the working circuit, the charging of the condenser being effected by a coil operated either by alternating or direct currents. By this means any desired higher frequency may be obtained from any lower frequency.

Mr. Tesla concluded his experiments by exhibiting in action a simple alternate current arc lamp, operated by currents direct from the machine giving 20,000 alternations per second. The light was beautifully steady and the arc entirely free from the hum accompanying arcs operated with currents of low frequency.

We have given but the merest outline of the many beautiful and highly suggestive experiments made by Mr. Tesla. Notwithstanding the fact that Mr. Tesla excited the intensest interest of his audience for three hours, he was nevertheless unable, for lack of time, to bring before them many experiments, some of which, he said, were even of a more striking nature than those brought out.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* The Electrical Engineer. *Communications for the attention of the editors should be addressed,* Editor of The Electrical Engineer, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

Vol. XI. NEW YORK, MAY 27, 1891. No. 160.

Many valuable inventions have been founded on the discovery of simple facts, but such inventions can never be perfected unless the principles of science upon which they are based are known.—Joseph Henry.

THE TESLA EXPERIMENTS.

WHILE the interest in all the papers of the annual meeting of the American Institute of Electrical Engineers was sustained throughout the sessions, there can be no question that most interest centred upon the lecture delivered by Mr. Tesla on the phenomena of alternating currents of high frequency. Mr. Tesla's recent utterances on this subject had served to excite the curiosity of many, and we believe that a thorough analysis of the work accomplished by Mr. Tesla, as exhibited in the experiments shown by him, will lead to the conclusion that those expectations have been more than realized. The brilliant researches and experiments inaugurated by Dr. Hertz, and followed up by Lodge and others, which served to verify the theory that the phenomena of light were referable to electro-magnetic vibrations of the ether, seemed to point out an apparently easy way of obtaining illumination directly through the medium of electro-magnetic vibrations. It has remained for Mr. Tesla, however, to recognize that for the production of light, electrostatic effects are needed. He reasoned that it was impossible to obtain primarily the desired electro-magnetic effects, since we must work with bodies of infinitesimal dimensions which can be acted upon only electrostatically, it being evident that an electro-magnetic wave cannot excite luminous radiation unless it be a true light wave. To produce longer electro-magnetic waves would, therefore, be of no avail; but this is not the case with electrostatic waves or thrusts. These, no matter what their length, Mr. Tesla demonstrates, can excite luminous radiation by disturbing molecular or atomic charges, causing the molecules or atoms to vibrate and to emit light; and since electrostatic effects are dependent upon the conjoint effects of potential and frequency, this reasoning led him to the investigations, the results of which were shown.

Continuing the train of reasoning followed by Mr. Tesla, we see that he has recognized further, that electrostatic effects of such character are available in many ways for the production of light. Thus he showed that if a filament in a globe be connected with only a single terminal of the source, in consequence of the rapidly alternating potential, the molecules of the gas are strongly attracted and repelled, and in this manner by their impact a filament may be kept at incandescence with only one wire. With these facts before him, and recognizing further that the employment of a filament is a bar to the attainment of higher efficiency on account of the limited degree of incandescence at which it can be run, Mr. Tesla reasoned that two blocks of a refractory material may be placed in a perfectly exhausted globe and sufficient energy transferred by condenser action to keep the blocks at incandescence, thus allowing a much higher efficiency in the production of light by reason of the possibility thus afforded of maintaining the carbons at a much higher degree of incandescence. Mr. Tesla has also shown that it is perfectly practicable to transfer sufficient energy to the medium, from a single block or filament placed in a perfectly exhausted globe and connected with one wire to the source, to keep the filament at the desired incandescence. Another and most important fact which he demonstrated was the practicability of using tubes of rarified gas without any terminals as practical sources of illumination by simply creating an electrostatic field near them, and also of using lamps without leading-in wires. All these results can evidently only be obtained by the use of enormous frequencies and potentials, or, in other words, powerful electrostatic effects, the study of which was made difficult in consequence of the fact that in previous experiments, looking to this end, the static effects were excessively small, owing to the fact that the coil was short-circuited through the low resistance discharge between the knobs of the discharger. The method of conversion devised by Mr. Tesla, allowing of the use of any frequency, enables us to undertake a much more exact and easy study of the effects of short waves. Again, his experiments with the lamps burning when connected with their terminals to a short, thick copper bar, are extremely interesting. The possibility of verifying nodes on the bar by simply using a Cardew voltmeter will be of great value in investigating these phenomena. His experiments also prove that while, with alternating currents of low frequency, such as are now generally employed, the effects of self-induction must be largely considered, those of high frequency accentuate largely the condenser effects which have to be allowed for accordingly.

It would lead us too far to enter into all of the numerous points suggested by Mr. Tesla's lecture, but he showed enough to warrant the assertion that in a comparatively short time the practical application of these principles to the production of artificial illumination will be an accomplished fact.

THE ELECTRICAL EXHIBIT AT THE WORLD'S FAIR.

The latest suggestion, and one that contains many points of merit, for the location of the electrical display at the World's Fair, is to place all the generating plant in a portion of the Machinery Annex. It is then proposed that a subway be constructed from the Machinery Annex to the Electric Building, in which all the cables and wires transmitting electrical energy for the respective exhibits of the various companies will be placed. In addition to this, the lighting of one or more of the buildings, or portions thereof, will be allotted to the various exhibitors of generating machinery to light and furnish electrical energy for operating motors, which will be used in large numbers for all kinds of service throughout the whole Exhibition, and the wires will be carried from each respective generating plant to the points designed for them to supply. The lines transmitting energy to the Electric Building, will supply current for every purpose required there. At first sight it might appear that the main portion of the electrical energy would be required in the Electric Building, but a moment's thought will show that this, however, is not the case, the proportion of power required for the exhibits being small in comparison with that to be distributed all over the Exhibition and grounds for lighting, power and traction purposes. For this reason, the amount of copper in the conductors connecting the Machinery Annex and the Electric Building, will not be abnormally excessive, although, of course, the extra expense would not have been entailed had the entire display been under one roof.

Strenuous efforts have been made from the outset to prevent a divided exhibit, and this newly suggested arrangement, should it be adopted, will practicably make the exhibit a twin one, the generating plant in the Machinery Annex being, of course, considered as a part of the electric exhibit.

AN ELECTRIC DISPATCH SYSTEM.

It has, for some time, seemed probable that one of the developments of the near future, in the way of transportation, would take the form of an electric dispatch system for carrying mails and certain classes of express matter at a high rate of speed between our principal commercial centres. Among the plans thus far proposed, perhaps the most unique is that of the Portelectric Company, of Boston, which may be regarded as a development, on electrical lines, of the pneumatic carrier system, which has long been in successful use in large cities for similar purposes. The report of Mr. Pope, which we reprint elsewhere, is, so far as we know, the first expert investigation of the actual merits of the portelectric scheme whose results have been made public, and the facts and figures given are of great interest. Mr. Pope's conclusions, though conservatively expressed, seem to leave little room to doubt the practicability of the system from a technical standpoint. It is true that the original cost of the plant must necessarily be greater than one in which traveling motors are employed, in accordance with ordinary practice, yet the absolute simplicity of the devices used, and the enhanced possibilities of speed which must result from the direct application of the propelling power to the carrier, are features whose importance may easily be overlooked at first sight. It certainly cannot be unreasonable to suppose that the factor of mechanical resistance in this apparatus can be reduced at least as low as that of an ordinary railway train, and granting this, Mr. Pope's predicted rate of speed of 150 miles per hour ought to be attained without difficulty, with the existing electrical appliances, at a very moderate cost for operating expenses.

We predict that the managers of the express and forwarding companies will be quick to see, in some such system as this, a possibility of enormously increasing the scope of their operations, for it needs but little consideration to show the practicability of a system of special delivery by which a letter or small package dispatched from New York could be delivered to the addressee in Boston within two hours, at a charge of ten cents or less, and yet leave a handsome profit to the carrier. That something of this kind will be done at an early day, and that such a system will divert a considerable share of the traffic that is now conducted by the mail and telegraph, there can be little reason to doubt.

The Meeting of the Electrical Engineers.

The annual meeting of the Institute last week was a success upon which the profession is to be greatly congratulated. In this issue we print such of the papers as are ready for publication—all of them excellent—and give a synopsis of the remarkable Tesla lecture. It will be noted also that the meeting did not lack in social success, for the reception at the Electric Club was an occasion long to be remembered. The Institute is happy, moreover, in its choice of Alexander Graham Bell for president. The office grows yearly in dignity and importance, and he will grace the leadership of a body of nearly 600 men in a profession of which his genius helped to create one of the leading branches.

New York Rapid Transit Plans.

It is now understood that the Rapid Transit Commission will report in favor of an 18 mile road, as nearly straight as possible, with two way tracks and two express, partly underground downtown, partly elevated, and partly viaduct, but with no surface track. With the express service, the total run will be made in 20 minutes. This road will be on the West Side all the way up. The main point of special interest to electrical engineers is that electric motors are preferred for the work, and that steam is not to be used. In this view of the situation, the Institute paper of Mr. F. J. Sprague is of unusual interest. It is a masterly effort anyhow, and shows how thoroughly Mr. Sprague has studied the problem. His determined fight for the adoption of electricity for New York's coming rapid transit now bids fair of early fruition. The mere rumor that the Commission has looked with interest at the operation of the "Bergmann" electric motor, shows that it is open to conviction as to the capacity of electricity to do the work.

Mr. Foster's Central Station articles will be continued next week.

THE PRACTICAL ASPECTS OF ELECTRIC WELDING.[1]

BY FREDERIC A. C. PERRINE, D. SC.

THE plant with which I have been intimately connected, though not one of the heaviest, is still one making a great number of successful welds in a day, and is one in which the joints are required to be of the highest character and are subjected to the severest tests. The first machine actually sold by the Welding Company was bought by the Roeblings. This was of the direct type, having a double winding on the armature, and the welding done on an apron immediately above the collector terminals of the heavy alternating coils; the pressure was applied by a handle regulated by the workman, the projection also being regulated by a scale stamped on the cam of the handle. Though considered crude, this machine did satisfactory work, often for 24 hours a day, and six days in the week, for about two years, having made about 370,000 splices in telegraph wire during its useful life.

After the automatic machines were brought to a reasonable perfection, we purchased a generator capable of welding up to ½ in. copper (40,000 watts), and installed one large transformer, and seven smaller ones of capacity from No. 4 B. & S. copper to No. 18 B. & S. These have been at the works something less than one year, and show a daily record of over 1,000 welds in copper and iron wire.

Messrs. Seward & Son, of New Haven, Conn., have at work a machine of somewhat universal character, its employment being principally in uniting Norway iron to Swedish steel, in such shapes as are required in carriage irons and fifth wheels. In this work the burr is removed by a drop hammer at the same heat by which the weld has been made.

The crescent tires of the hundreds of bicycles manufactured by the Pope Manufacturing Company, are welded and afterwards formed by dies at the same heat. The material is soft steel. These people also have a machine for brazing their small parts.

Besides using the electric welding machine for their telegraph wire, the Trenton Iron Company, of Trenton, N. J., have boldly attempted to make a weld in a wire rope to avoid the tedious, and, with their locked wire rope, impossible, operation of splicing. With the locked wire rope, which is itself but a single strand, the only successful method of joining opposite ends has been to fasten securely around each a cast-iron collar, and after abutting the ends in a welding machine, to cement the whole together and afterwards to break off the cast-iron collar, leaving the rope as a solid bar for about 2 in. at the weld.

Among the new solutions of old problems accomplished by the electric welding process, is that of the manufacture of spinning rings by the Hopedale Machine Company, of Hopedale, Mass. With a welding machine it is possible to form these little rings, about 2⅛ in. diameter, from a piece of bar iron, and after the burr has been reduced by a series of dies, to finish as before, with the result of a decreased cost, and an equally satisfactory product.

One of the largest and most complete plants at present in operation is that of the Studebaker Bros. Manufacturing Company, of South Bend, Ind. They have at present nine machines; one of them for steel axles up to 1⅛ in. square. After the weld is made it is quickly removed to a drop hammer, making about 300 blows a minute, then at the same heat the axle is set ready for the market. The test for these axles is to bend to 90° while hot, and then back to alignment. No instance has yet been reported of an axle breaking under this test, which is frequently made to insure perfect workmanship.

They have also two machines for welding large car tires, about 4 ins. wide and ¾ in. thick, and smaller sizes. The weld is made in the usual way and then quickly removed to a hammer, where, by vertical and side blows, the burr is quickly removed. One hammer will easily take care of two welders in constant operation. They also have one machine for small carriage tires, 1 in. x ¼ in., and smaller sizes. In this case the burr is removed by one blow of the hammer.

Probably the heaviest work done at present in electric welding, is that of the Johnson Rail Company, of Johnstown, Pa. As to their results in general, they say: "We would state that over a year ago we put in one welder for general work. The result of a year's use of the electric welder was, that we have not known one of the welds made by the method to fail, and we have closed contracts with the welding company for four 40,000 watt machines and two 89,000 watt machines, with the intention of adopting the method extensively in our works."

The hardest steel at present successfully worked by this process is the welding of band saws by the E. C. Atkins Company, of Indianapolis, Ind.; besides the regular work of making the joint in continuous band-saws, these people have ingeniously adopted this method for replacing broken teeth in finished saws.

Pipe welding is put in practice by the Pennsylvania Railroad Company, as well as by the Columbus Iron Works, Columbus, Ohio; Blymyer Ice Machine Company, Cincinnati, Ohio, and the Electric Pipe Bending Company, of Newark, N. J. This latter company is engaged principally in manufacturing long continuous coils for ice machines, blast furnace tuyeres, and radiators. With this machinery they not only weld extra heavy black pipe, but also electrically heat the pipe with a machine 20 in. between the clamps for the purpose of bending to desired shapes over pipe formers.

With continuously spiraled coils of pipe, under the present electrical methods, the coils are continuously heated in a fire, and the coiling is continuous while one length of pipe is welded at a time, the operation being to attach the welding machine to the end of the moving pipe, and while the forward portion is undergoing the process of bending, to weld on a new length, which will be accomplished in a sufficiently short time not to interfere with the coiling apparatus. In all this pipe welding the burr is beaten down by means of a pneumatic hammer, which is put in rapid motion by the act of closing it around the pipe.

Three types of machines of importance are soon to be in use for the purpose of our army and navy, and the early recognition of the importance of this method of manufacture, speaks well for the ingenuity of our government designers.

In the new wire-wound guns one of the most important specifications for the wire was that it should be readily jointed by the electric welding process, and in the Crozier gun, now constructing, the wire will be wound in one continuous piece under a constant and heavy strain. This wire is one-tenth in. square, with 180,000 lbs. breaking strength, and 100,000 lbs. elastic limit, tinned as lightly as possible. The gun is to be made by winding the wire over a steel tube and shrinking a ring over the whole, for the purpose of longitudinal strength; the welding process is simply the same as that described for round wire, and is reported as having given satisfactory results.

For the Charlestown Navy Yard there is about completed a machine for welding ship chains up to 2 in. diameter links. These links are formed in halves and fitted roughly to each other, the welds being made in both sides at once by the same heat, which can be regulated to force either side at the will of the operator. When completed, both welds are forged immediately in a die by the same hammer.

Electrically welded shells are made entirely of forged point, body and base, which may be finished to approximate dimensions, these requiring after welding a minimum amount of machining. The tests on these shells have resulted in a contract for a large number under a guarantee of the manufacturing company.

The electric welding process uses rather the method of the crucible than of the press, for although considerable pressures are applied during the operation, they are not beyond the limits of ordinary forging, and the essential difference is the greater heat available at the direct point where it is most needed, a heat which approaches and often reaches the melting point of the material. As the pressure is applied it is transmitted by the cold bar directly upon the softened metal and forces it to unite more readily. This view of the process brings us at once to some of the most important limitations; cast-iron, cast-steel, cast-copper, cast-brass, are not changed in their essential constitution, but are united by a weld having all the characteristics of the original bar. Now let us take a bar of rolled zinc or drawn copper and compare it with the cast metal. We find the crystals, formerly large, and widely separated, especially in the case of zinc, where often internal oxide stains are perceptible, now are broken into minute fragments, elongated and united so closely as to allow the greatest opportunity for the action of cohesion. Weld such a metal as this, and the joint where broken will immediately show a re-arrangement of the particles into larger and looser crystals similar to those of the unworked metal. By repeated fracture of the bar, you will be able to follow graduations of the action till it loses itself.

A weld of this character will give a sufficient tensile strength, but the brittleness of a coarsely crystalline material has returned. Whether such a joint is worthless is entirely a matter of circumstances. With small sections the action is not perceptible on account of the very small length heated, and also because bending, however short, does not subject the metal to so great a strain as is the case with larger sections. For a rod to be subjected to further drawing, rolling, or other like processes of manufacture, the weld is satisfactory, since the subsequent working reinstates the metal to its best condition, but for a wire to be considered a finished product, further manipulation is necessary. In view of this, the later machines for welding heavy copper have been provided with reheating clamps and light rapid hammers, by means of which the burr, after a slight trimming, can be reheated and forged; in special cases a further hammering cold is added. Though this produces a great improvement in the metal, it yet leaves a good deal to be desired where great strength and pliability are required. To produce this, a further upsetting of the metal throughout the whole heated space, and a subsequent forging will be necessary. This, up to the present time, has not been provided for, and presents a greater difficulty than is at first apparent, besides furnishing a new proof of the crystalline constitution of copper. On account of this characteristic, as is apparent on attempting upsetting in the welding machine, it offers, at a red heat capable of moving and re-arranging the particles, a resistance to compression so high, that three or four times the pressure necessary for welding will not have the slightest effect towards increasing the diameter or upsetting. With bronzes the further difficulty is encountered of red shortness between the molten temperature of the weld, and the malleable red temperature. That this should be so necessary and offer so many difficulties may seem strange, since the metal does not apparently exceed the temperature of ordinary annealing, and it must be that either the passage of the current by an extra disturbance helps to re-arrange the particles, or else the temperature is greater than we imagine from an observation. The latter explanation seems to me to be the more likely, since our ordinary observations are made on metals heated from an external source, and of which the surface is at the highest temperature. With the weld, however, the source of heat is internal, and the surface is undergoing a continual cooling from the external air.

---

[1] Abstract of a paper read at the General Meeting of the American Institute of Electrical Engineers, New York, May 20th, 1891.

Welds made in the higher carbon steels are at a similar disadvantage, and must be looked upon with disfavor unless provision for upsetting and forging hot is made.

This brings us to a point where the electric welding throws light upon the actual production and nature of burnt steel. By forcing the heat in welding, no matter if rapidly, this effect can be produced as thoroughly as by the means of a fire, while if the name "burnt" was an accurate description, and the iron and carbon oxidized, a sufficient time would be necessary for its penetration into the centre of a bar of metal. This agrees with and is a further confirmation of the most modern ideas about burnt metal, that it is a molecular re-arrangement, and by careful forging and heating the metal can be restored to its original state. In this case oxidation certainly does not take place, though the action may be similar to metamorphism in rocks; steel being at the present day looked upon as a mineral, a matrix of iron including minerals which are generally compounds of iron with carbon, silicon, sulphur, manganese or phophorus. Under this view there may be internal chemical re-arrangement at high temperature. With carbon we know this to be the case, but I take it as settled by electrical heating that the change is not necessarily an oxidation.

The welding of two different materials, such as iron and steel or malleable cast-iron, presents another difficulty and possible danger. When such a weld is broken we find that the pressure in the plastic slate has forced the iron over the steel or malleable, which has itself been merely slightly melted and cemented to the adjacent particles of the iron. This produces what might be called a reverse rivetting, the hot iron having been upset over the steel and enclosing it tightly, in the place of having been upset in a hole as in ordinary rivetting.

A STUDY OF AN OPEN COIL ARC DYNAMO.[1]

BY MILTON E. THOMPSON.

In carrying out this work no attempt has been made to determine the efficiency of the dynamo, or to determine an answer to the question, Is the machine well suited for arc lighting? The vast numbers of these dynamos in daily use in all parts of the world is a practical answer which must carry more weight than any which might be suggested by a theoretical study of the machine. The experimental work of this investigation was carried out under the direction of Prof. Nichols in the laboratories of Cornell University, during the past winter, by the writer, with the assistance of Mr. H. J. Hotchkiss and Mr. E. L. Morley, and due credit must be given to these gentlemen for any points of interest which may have been brought out by the investigation.

The object in view was to determine accurately, by taking instantaneous values throughout the revolution, the character of the external and internal currents and electromotive forces.

The capacity of the dynamo in question was about ten arc lamps of 1,200 c. p. In order to carry out this work it was necessary to build a special commutating device of a character somewhat similar to a number of others before used in the Cornell laboratories for taking instantaneous values of current and potential.[2]

Three sets of curves of exterior current and potential were taken with three different loads upon the machine, and three sets of curves of current and potential through a single coil were taken with the same loads. In order to keep the electromotive force as nearly constant as possible, and prevent variations while a set of observations were being taken, the machine was loaded with a German-silver resistance. The loads consisted of about 20, 50, and 80 ohms, respectively, and were equivalent to about three, six and ten arc lamps. The current for all loads was supposed to be practically constant, and an ammeter placed in the circuit showed but little variation from the normal current of 6.8 amperes. A condenser and ballistic galvanometer were used for making the measurements, and Fig. 1 shows a diagram of the connection of the dynamo and also of the measuring apparatus. Referring to the diagram, A is the armature, FF the field coils, M the regulator magnet, C the controller magnet, and *r* the carbon resistance used to prevent excessive sparking at the contacts *k*; P is the positive terminal of the machine and N the negative, B is the German silver resistance which constituted the load for the dynamo, and *t* is a resistance of about one ohm placed in the circuit to serve as a basis for the current measurements. LL and SS are the brushes of the dynamo, which bear against the three segments of the commutator, as shown in the diagram; D is a condenser, K a discharging key, and J a small spring switch; G is a ballistic galvanometer, through which the condenser was discharged, and T is a shunt box for regulating the throw of the galvanometer and bringing it within proper limits. From the negative terminal of the machine, N, runs a wire to the commutating device, *c s*, and from that to the switch, J. From the positive terminal, P, and the binding post, B, run wires to *f* and *g* of the switch, *fgh*, as shown. From *g* of this switch runs a wire to the discharging key, K.

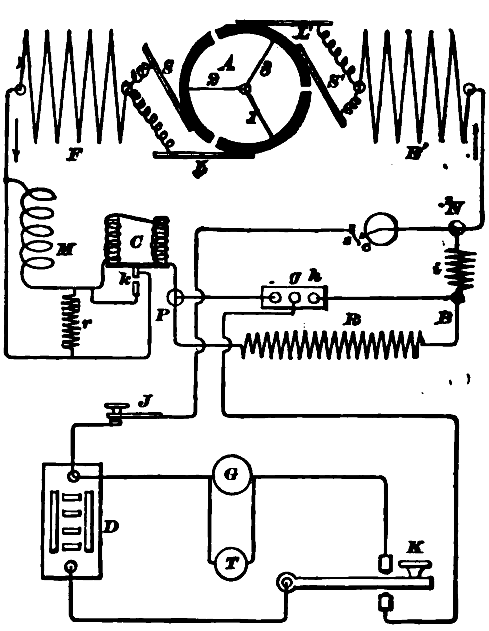

Fig. 1.

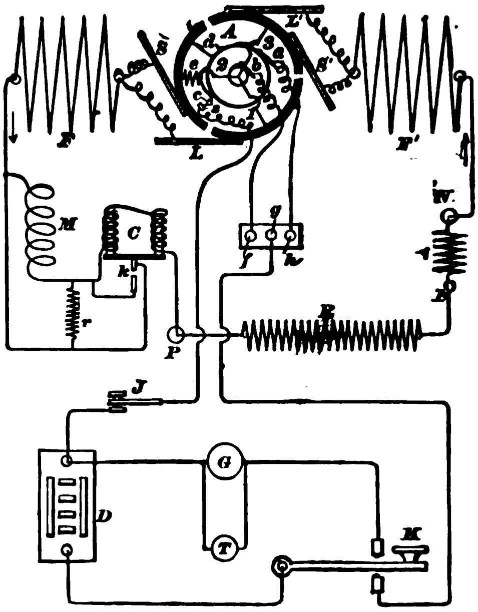

Fig. 2.

During these experiments the regulator was allowed to act just as in ordinary practice, but each load was constant and practically non-inductive. Three sets of curves of external current and potential were taken and the measurements were made in the following manner: The commutating device, C S, being secured in a fixed position, *f* and *g* were connected. The discharging key, K, being then depressed, switch J was then closed and in a few seconds the condenser became charged with the difference of potential existing between the terminals of the dynamo at the particular point of the revolution of the armature represented by the position of the commutating device. Switch J being then opened, the discharging key, K, was allowed to rise, and the condenser was thus discharged through the galvanometer, G, causing a deflection which was duly noted. The connections of the switch, *fgh*, were then changed so that *g* and *h* were joined, and in this way the condenser was charged with the difference of potential existing between the points B and N of the external circuit, at the same point of the revolution as the first reading. The condenser was then discharged through the galvanometer and the deflection noted as before.

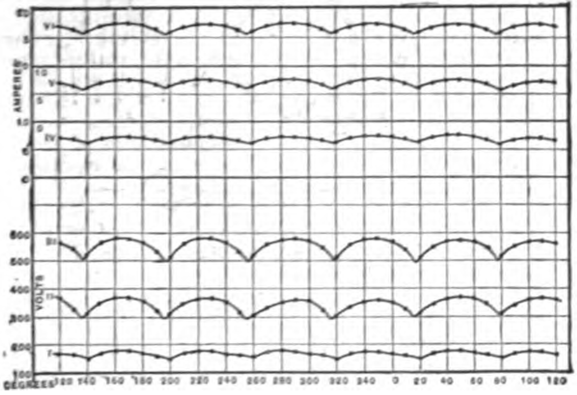
[1] Abstract of a paper read at the General Meeting of the American Institute of Electrical Engineers, New York, May 21st, 1891.

[2] TRANSACTIONS, Am. Inst. Elec. Eng., vol. vii, p. 3.

Fig. 3.



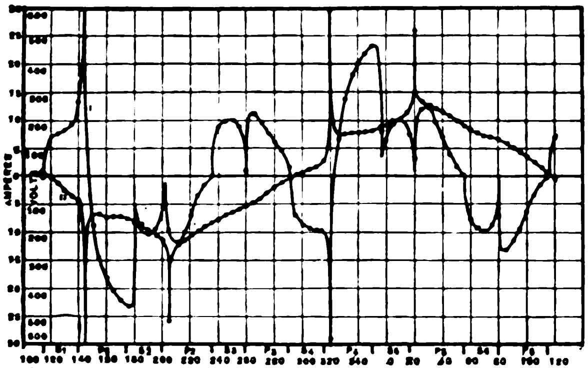


Fig. 4.

After moving the contact spring, *s*, forward ten degrees, the measurements just described were repeated, and so on until the contact had been moved entirely around the circle.

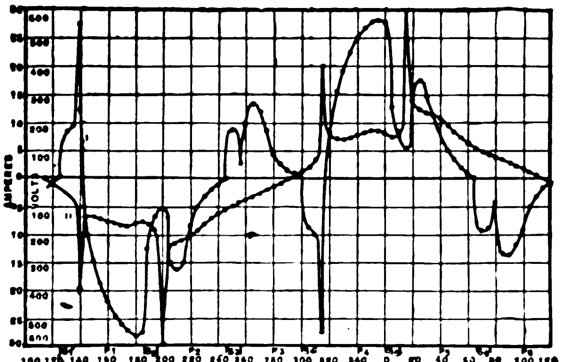

Fig 5.

The condenser and galvanometer being properly calibrated, it was an easy matter to calculate from the data obtained as above, the difference of potential between the terminals P and N, and between B and N, at 36 points of the revolution of the armature. The resistance between B and N being known, the current was readily determined from the fall of potential. The results of these measurements are shown graphically in Fig. 3, and will be referred to later.

After taking curves of the exterior potential and current, the apparatus was arranged for measuring the potential and current in a single coil of the armature. Coil number 2 was selected as likely to present results nearest the average of all three of the coils, and the apparatus was arranged as shown in Fig. 2. The circuit of the dynamo and its loads were exactly as for the first measurements, and the connections of the measuring instruments were as shown in the diagram.

Readings were taken at distances of five degrees apart all around the revolution and the results are plotted out in Figs. 4, 5 and 6, three curves at three different loads being taken as before.

Turning now to the results obtained in Fig. 3, curve I represents the difference of potential at the terminals of the dynamo throughout the revolution under a light load, and curve IV is the corresponding current. Curve II is the potential for medium load and curve V the corresponding current, while curves III and VI represent the potential and current at full load. It will be noticed that the curves for medium and full load are practically alike, while the current for light load differs slightly in its character and is less symmetrical, and its minimum points occur slightly later than in the other curves. The curves of current and potential are practically alike, as might be expected, since the self-induction of the external circuit was little or nothing. The curves are all of them about such as would result from a closed coil armature with a six part commutator. These curves show that the external current is continuous and much steadier and more uniform than is usually supposed.

Fig. 6.

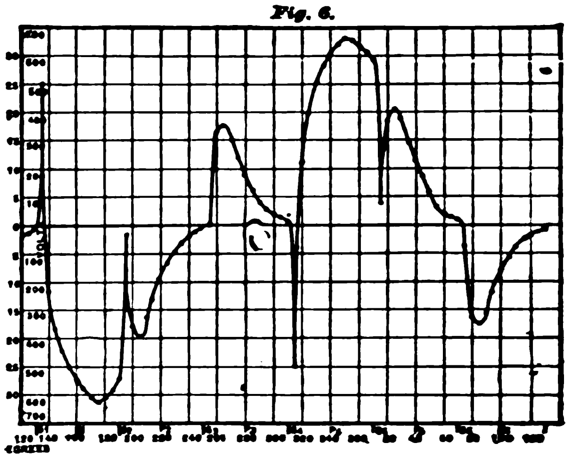

Fig. 7.

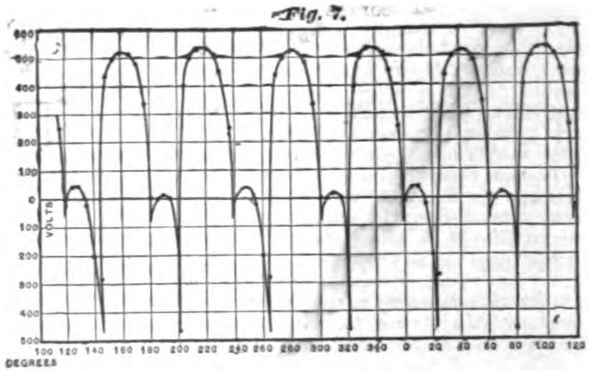

Referring to Fig. 4, we find that the state of affairs in a single coil is quite different from that at the terminals of the dynamo. Curve I represents the difference of potential at the ends of the coil throughout the revolution, and curve II is the current in the same coil during the revolution. The curves shown in Fig. 4 were taken with a light load. Figs. 5 and 6 show curves taken with medium and with full loads. For some unknown reason it was found impossible to get accurate readings for the current at full load, and so no current curve is given in Fig. 6. It is probable, though, from the similarity of the current curves at light load and at medium load, that the current for full load differed very little from the other two.

It will be noticed that at all loads the potential changes sign no less than six times during the revolution and falls to zero, or almost to it, as often as twelve times, while the current reverses but twice during the revolution and for the most part goes through very gradual changes. At the bottoms of the figures are lines of spaces showing the positions of the armature during the part of the revolution represented by the curves above them. s_1, s_2, s_3, etc., are the periods of short circuit and p_1, p_2, p_3, etc., are the periods during which two coils are usually supposed to be in parallel with each other and in series with the third coil. There are six periods of each kind in the course of each revolution. Figs. 10, 14 and 18 represent the relative positions of commutator and brushes at the three different loads during the parts of revolution shown at s_1. For the light load this period is about 25°; for the medium load about 10°, and for full load not more than 1°. The periods shown are not the *actual*, but the *apparent*, periods of short circuit as it would seem to be from the positions of the commutator and brushes. The *actual* periods of short circuit are somewhat longer, owing to the conductivity of the spark, and last until the spark is blown out. The exact point of the revolution, represented by Figs. 10, 14 and 18, is the point 130°, as marked below the curves. Figs. 11, 15 and 19 represent the positions of the brushes and commutator for the parallel periods p_1, or, to give the exact position shown, 160°. Figs. 12, 16 and 20 represent the second short circuit period, s_2, or 190°, and Figs. 13, 17 and 21 show the second periods of parallelism, p_2, or 220°. In all of these figures the relative positions of the coils and poles of the dynamo are also shown, the coils being numbered 1, 2, 3, just as they are on the dynamo. During the entire period represented by each four figures as above, the armature has turned through 120°, or one-third of the revolution, and if we now consider the position of coil 2 changed to that of coil 1 in each figure, our figures will then represent the next third of the revolution. If coil 3 is supposed to occupy the position of coil 1, we shall then have the remaining third of the revolution.

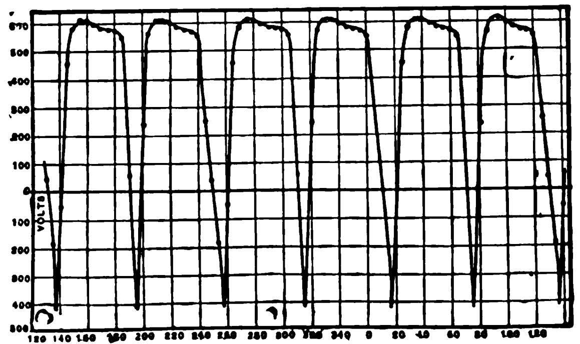

Fig. 8.

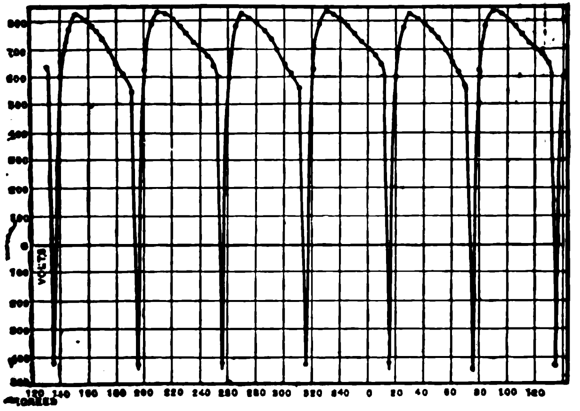
It will be noticed that the more sudden and violent changes of potential occur just as the spark is forming and being broken at the front end of the commutator bar.

In examining these curves of potential it should be remembered that they represent the *difference* of *potential* at the ends of the coil and *not* the E. M. F. developed in the coil during the revolution.

Fig. 9.



It will be noticed that the direction of the currents in the various coils for the so-called periods of parallelism and short circuit is quite different from what would be naturally expected and from what has been supposed to be the case in most of the descriptions of the action of this machine. It will be seen that there is no instant during the so-called parallel period when coils 1 and 3 are in parallel and that the *actual* parallelism does not occur until after the beginning of the period of short circuit. In the case of medium and full loads, however, it occurs at from 10° to 20° before the period of short circuit. Another point worthy of notice is, that at the first instant of short circuit, when the commutator bar just touches the following brush, there is no sudden increase of current, as would be naturally expected, but the current in the short circuited coils slowly and gradually increases until the short circuit is broken by the blowing out of the spark, at which instant the current is a maximum in the coil whose commutator bar is opposite the sparking point, and in the other two coils it is about the same as the normal external current.

In Figs. 7, 8 and 9 are shown curves of potential at the brushes, at the three different loads. These curves were obtained from the potential curves of Figs. 4, 5 and 6, by adding together the potentials of the three coils according to their relative positions, and thus obtaining the potential at the brushes. It will be noticed that at all loads the curves fall below zero six times during each revolution, and that the difference in area, and consequent effective E. M. F., is obtained more by the widening out of the curves than by increase in height. This is what we ought to expect from the change in duration of the short circuit periods. A comparison of these three curves of potential at the brushes, with the three curves of potential at the terminals of the dynamo will give one a good idea of the remarkable steadying power which magnets such as the fields of this dynamo, exert upon an intermittent current. No further explanation is needed of the fact that this dynamo will not work as a separately excited machine. The whole set of curves will serve to illustrate some of the very remarkable effects of armature and field reactions and any one sufficiently interested to make a detailed study of them might possibly succeed in bringing out a number of curious and interesting, if not useful, results.

AN ALTERNATE CURRENT POTENTIOMETER.[1]

BY GEORGE S. MOLER.

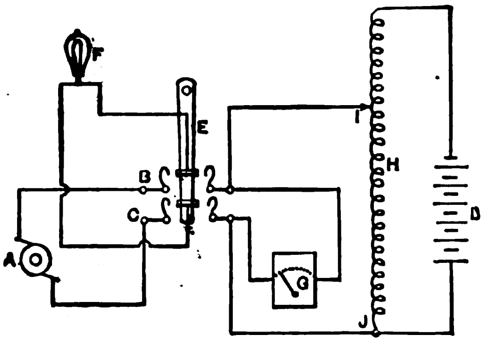
THIS device is designed for the purpose of determining what values of the potentials of alternating currents will produce given effects, and is intended to be used mainly in calibrating alternate current voltmeters. It may also be used as a voltmeter, applying it directly to the alternate current to be measured. By means of this apparatus we may determine whether the instrument which is being calibrated changes its reading for other rates of alternations. This is shown by comparing the calibration curves obtained by using widely different rates of alternations.

The instrument, briefly described, is as follows: An incandescent lamp is so arranged and connected that it can be switched back and forth from the terminals of an alternating current line to those of a direct current line, which can be altered in voltage till the lamp glows with the same intensity when fed by either line. Then, while switched into the direct current line, the voltage of that line is measured by a direct current standard voltmeter or potential instrument, and the voltage so read is equivalent to that of the alternating current, which produces the same effect in the lamp. The switch is so constructed that it snaps back and forth, making the change of connection so quickly that the slightest change of intensity of the light can be easily detected. The lamp has a blackened hood with an opening in one side through which it is viewed while the sliding resistance is being adjusted. This enables the observer to make a much closer setting than otherwise. A very close setting may also be made by observing the slight reflection of the light from the blackened surface of the hood.

---

[1] Abstract of a paper read at the General Meeting of the American Institute of Electrical Engineers, New York, May 21st, 1891.

The lamp and switch are arranged and connected in the following manner: Referring to the diagram, A is the alternate current dynamo, or line, of which we wish to determine the effective difference of potential in volts between its two terminals, B and C; D is a storage battery or direct current dynamo of higher voltage than the alternate current to be measured. A switch, E, made to snap back and forth by means of a stiff spring, changes the incandescent lamp F, from the alternating current to the direct current and vice versa. By connecting the two extremities of a resistance, H, to the battery, D, and sliding the contact point, I, such a place can be found that the intensity of illumination will be the same for both currents. After the contact I is adjusted, the standard voltmeter, G, is read while the direct current is flowing through the lamp, and this voltage is taken as the equivalent voltage of the alternate current.



MOLER'S ALTERNATE CURRENT POTENTIOMETER.

A series of lamps of different voltages affords a greater range to the instrument than could be obtained with one lamp only. These may all be connected to the switch, and, beginning at the one of highest voltage, one after another may be tried till the best one is found. For higher voltages than the highest voltage lamp will stand, a number of lamps may be used in series, and the fall of potential for all, or for each individual lamp, can be measured by means of its voltmeter. The resistance H, must necessarily be great enough in amount so that only a small current will be allowed to flow through it, so that the comsumption of energy will be small.

Instead of having the switch and lamp connected in a shunt line to the resistance H, it may be connected in series with H, which must then be arranged so that it can be varied in amount. If a source of constant potential large enough in amount is available, the apparatus may be used for a voltmeter for direct or alternating currents. To use it in this manner, we calibrate the apparatus to find the potentials at the terminals of the lamp for different positions of the contact points I and J, and construct a curve, using the positions of I and J as abcissæ and the differences of potential of those points as ordinates. Then, when using the apparatus as a voltmeter, we read the values from this curve instead of from a voltmeter connected to the switch.

Upon this instrument readings could be estimated to one-tenth of a mm., giving volts to the second decimal place. The accompanying table of results were the first part of the first set taken without any preliminary practice. From this it will be evident that the adjustment of the light can be made to within one-tenth of a volt.

A NEW GRAPHICAL METHOD OF CALCULATING LEADS FOR WIRING.[1]

BY CARL HERING.

THE following suggestions of a graphical method is an attempt to reduce this work to what might be called "machine methods," by substituting for the usual figuring, a simple graphical device which requires no figuring at all and which is, at the same time, universal in its application, as it is adapted equally well for any of the many different lamps in the market to-day.

Makers and users of one particular lamp can readily calculate a wiring table for that lamp, for each of a few of the usual losses in the leads, and such tables are often quite convenient for those particular conditions; but it is evident that they are limited to those fixed conditions. As long as there are lamps of such different amperage and voltage, it would hardly be practicable to make a universal set of tables, especially when the currents which the lamps take are greater than what is claimed for them. Graphical methods, therefore, suggest themselves, for in these the size of the diagrams does not increase nearly as rapidly for an increased scope as the number of tables would. Graphical methods have been devised to replace the tables, but they have not been satisfactory for various reasons.

The present method is an improvement on the one described by the writer in THE ELECTRICAL ENGINEER of Jan., 1887. The general principle may be laid down that for any formula containing three variable quantities, one of which is the product or the quotient of the other two, the "curves" representing their relative values may always be represented by a series of straight diagonal lines drawn through the centre or zero point. Such a set of lines will therefore enable one to make any calculations graphically for that formula. For instance, horse power is equal to volts multiplied by amperes; the constant 746 does not concern us at present. A series of diagonal lines properly spaced will therefore give directly either the horse power, the volts or the amperes, when the other two are given. The curves may also be made hyperbolas, but it is evidently absurd to draw hyperbolas when straight lines answer just as well and are even more accurate, as they can be laid off and drawn with great precision. Notwithstanding this, such diagrams are often published as hyperbolas.

Now, the general formula for wiring is as follows:

$$\text{Cross-section} = \frac{\text{current for one lamp} \times \text{number of lamps} \times \text{distance} \times \text{constant}}{\text{loss in volts.}}$$

containing six quantities, only one of which is always constant, being equal to twice the mil foot resistance of copper, if the cross-section is in circular mils. For instance, for any one make of lamp the current per lamp is a constant, and may therefore be combined with the other constant as one; if, furthermore, the number of lamps and distance be multiplied together mentally and then used as one quantity, lamp feet, there are then only three variable quantities to the formula, and calculations can then be made by one set of diagonals. This will give the diagram mentioned in the early part of this paper. But a universal diagram must be equally well applicable to any lamp; and as graphical calculations are so much simpler, more rapid, and less liable to error than arithmetical ones, it is preferable to multiply the lamps by the feet graphically also. Both of these may be accomplished by splitting up this formula into smaller ones, each of which contains no more than three variable quantities. Each formula can then be calculated separately by a simple diagram, as described, thus permitting the whole formula to be calculated graphically.

To do this, let the first diagram perform the calculation,

$$x = \frac{\text{current for one lamp}}{\text{loss in volts,}}$$

in which x is a mere auxiliary quantity. Let a second similar diagram perform the next calculation:

$$y = x \times \text{number of lamps};$$

and a third diagram the final calculation:

$$\text{Cross-section} = y \times \text{distance}.$$

The constant may be combined with any one of these; it is immaterial which one. This triple calculation may at first seem to complicate matters on account of the new quantities, x and y. These, however, are easily eliminated by the simple device of placing the three diagrams together, side by side, in such a position that the two x scales coincide, and similarly the two y scales.

In the accompanying diagram the formula just given is represented graphically as described. It will be seen to consist of three right angles, each with its set of diagonals and a common centre. Each two right angles have one side in common which represent the quantities x and y, and which thereby drop out of consideration. The lower left hand diagonals represent *loss* in

---

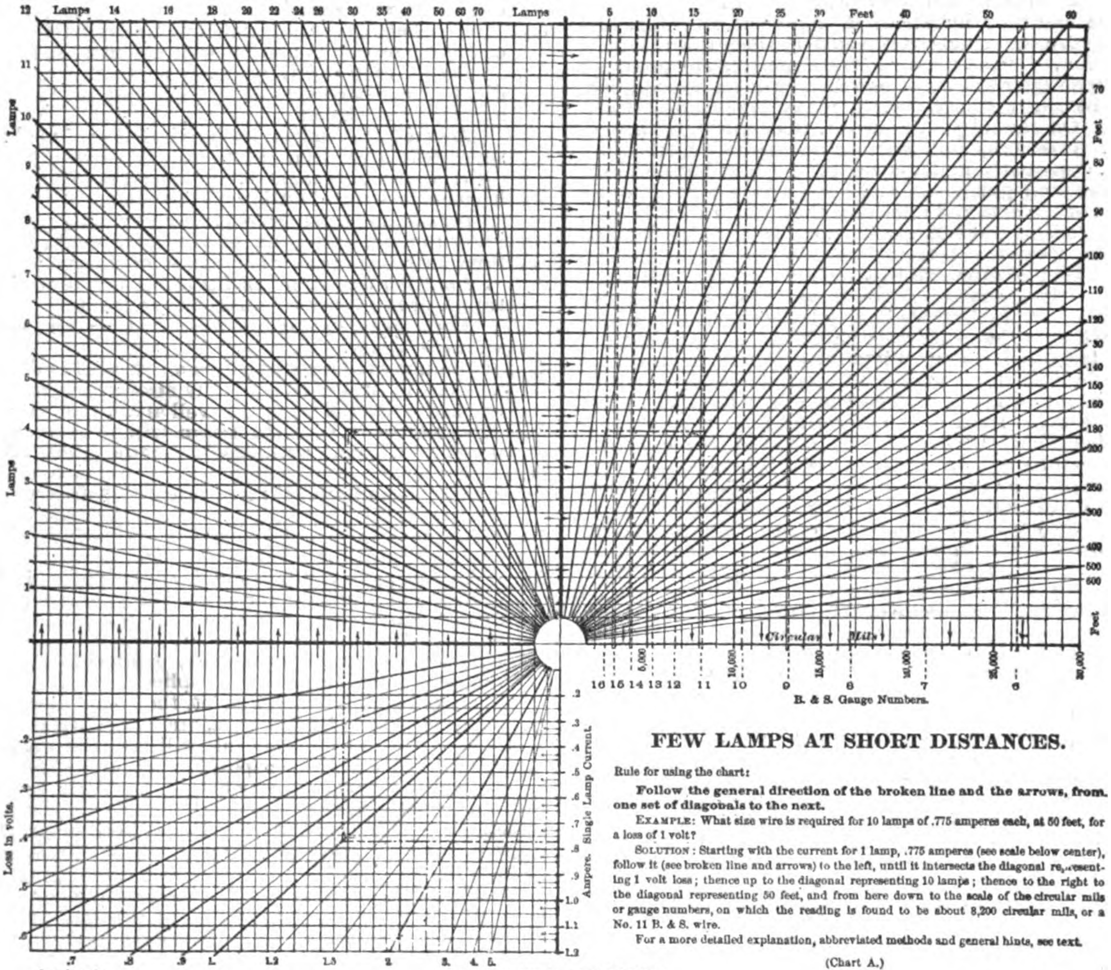
[1] An abstract of a paper read at the General Meeting of the American Institute of Electrical Engineers, New York, May 20th, 1891.

volts, the upper left hand, *number of lamps*, and the upper right hand, *distances*. The remaining two of the five variables are represented by the starting scale vertically below the centre, which represents the *amperage of a single lamp*, and the last scale, to the right of the centre, which represents the final result, namely, the *cross-section*. The constant is included in any one of these three sets.

To perform the graphical calculations, simply follow from one scale to the next on the cross-lined brackground up to the last scale, the cross-sections, which is the final result sought for. An example is worked out and illustrated by the broken line on the diagram. Starting first with the amperage of the particular lamp, .775, on the first scale, follow to the left (see the broken line) to its intersection with the required volt diagonal, 1.0 volt; thence up to the next diagonals, the lamps, 10 lamps; thence to the right to the feet diagonals, 50 feet; thence down to the scale of cross-sections, where the reading is about 8,200 circular mils, or about a No. 11 B. and S. wire; the whole operation requiring about as much time as it would take to start the arithmetical calculations.

The relative disposition of the scales is also of importance in such a diagram. For instance, the amperage of the lamp is generally the same for a great many computations; it has therefore been made the first scale, so that it can be eliminated from all those computations by drawing a horizontal line, say in red ink, through this value and then starting all the calculations from this line, thus saving that first part of the work. Next to the amperage of the lamp, the loss in volts is often the same for many calculations; the volt scale has therefore been made the second one, so that it also may be cut out of these calculations. To eliminate this part, draw a vertical red line through the intersection of the ampere and the volt lines. All such calculations are then started directly from the intersection of this line with the lamp scales. Finally, by the dotted lines drawn through the last scale, as shown, representing the cross-sections of the standard wire gauge sizes, the last part of the work is also saved. The only operation left to be performed, therefore, is to follow a horizontal line from the number of lamps to the number of feet; it would hardly be possible to have it simpler. As the majority of calculations are made for the same amperage of loss, this represents the most frequent conditions under which the diagrams would be used.

The range of such a diagram can evidently be made very great by having several sets of numbers on the scales; each set being, say, ten times larger or smaller than the other, the position of the diagonals will remain the same. By an accidental coincidence the position of the dotted lines representing the B. and S. gauge numbers, will also remain very nearly the same for different scales of circular mils, even though they represent different gauge numbers. Furthermore, lamps and feet are interchangeable on the diagram. Although the same diagram may have several different sets of numbers, it is probably preferable to have a separate diagram for each set. A set of three diagrams, of which the accompanying is the first one, will probably cover the usual ranges. For motor currents the same diagrams may be used, by assuming that the current represents that number of one-ampere lamps.



FEW LAMPS AT SHORT DISTANCES.

Rule for using the chart:

Follow the general direction of the broken line and the arrows, from one set of diagonals to the next.

Example: What size wire is required for 10 lamps of .775 amperes each, at 50 feet, for a loss of 1 volt?

Solution: Starting with the current for 1 lamp, .775 amperes (see scale below center), follow it (see broken line and arrows) to the left, until it intersects the diagonal representing 1 volt loss; thence up to the diagonal representing 10 lamps; thence to the right to the diagonal representing 50 feet, and from here down to the scale of the circular mils or gauge numbers, on which the reading is found to be about 8,200 circular mils, or a No. 11 B. & S. wire.

For a more detailed explanation, abbreviated methods and general hints, see text.

(Chart A.)

HERING'S WIRING CHART.

VISIT TO THE CROCKER-WHEELER FACTORY.

The members of the Institute met at the Crocker-Wheeler Company's, at 9:30 o'clock, on May 21, and were shown through the shops. They saw the manufacture of electric motors as carried on by that company, and as described and illustrated in last week's issue of THE ELECTRICAL ENGINEER. A table holding eight motors, ranging in size from 1/6 to 1 h. p., all exactly of the same type, made quite a harmonious exhibit as illustrative of gradations in size. One of the novelties, however, which pleased the members of the Institute very much was the new arc motor with perfected governor. A Silsby 100 gallon per hour rotary pump, connected to a ¼ h. p. motor, and one combination pump of the same make, coupled direct to the armature of the motor, worked to perfection. The self-governing device which this company has for pumping water to the tops of houses, and automatically shutting off the circuit when the tank is full, was shown on one 150 gallon, Gould triplex pump connected to a ½ h. p. motor, and one 225 gallon per hour Gould pump connected to a 1/6 h. p. motor. A La Rue combination exhaust air blower fan was shown, mounted on the window sill. This combination is very compact.

CONSIDERATIONS WHICH SHOULD GOVERN THE SELECTION OF A RAPID TRANSIT SYSTEM.[1]

BY FRANK J. SPRAGUE.

It has been but a short time since the Legislature of New York, in response to public demands as voiced by the press, in petitions, and through the personal efforts of the representatives of this city, enacted a rapid transit law to create a Board of Commissioners with large powers for the purpose of determining rapid transit routes for this city.

During the past three months the Commission appointed under this law has held numerous public meetings, at which various systems have been proposed. These meetings are now practically at an end, and it is currently reported that a portion at least of the rapid transit routes have been determined. Since this subject of transit is one which has a most important bearing upon present and future New York, and is one in which the public has vital interest, it is eminently proper that so much of the Commission's deliberation as have through its chairman been reported should be the subject of public comment and critical analysis.

The public is naturally impatient in demanding results, and has been unduly free in criticisms directed against the members of the Commission, often assigning to them motives and proposed actions based upon their known or assumed business associations, which criticisms are undoubtedly, in many instances at least, wholly unjust. On one subject, however, that public is particularly sensitive. It sees the daily encroachments made by the Manhattan system, apparently under cover of the law but in direct violation of its express provisions, and has no reason to be other than suspicious of the acts and intents of that corporation.

Probably there is no more flagrant example of this than the present work being carried on from 59th street up, on the Harlem division. Already the cross girders connecting the two track structures for nearly the entire section from 72d street, to above 155th street, have been replaced by heavy lattice girders on which are supported either lattice or plate longitudinal girders, for a third track. On a large portion of this section the third track has already been laid. The method adopted seems to be the construction of a switch connection of moderate length, the connection of which with the main track is eliminated as soon as another adjoining section is completed. The rapid transit law expressly forbids the laying of any third track except with the concurrence of every member of the Commission, and since no steps are taken to prevent this construction, and since it seems likely that the Manhattan Company would not go to the expense of making this change without some assurance that it would have the necessary permission granted to it, or that it would not be interfered with, the public naturally ask, What is the influence possessed by this company? How far does it dominate the Rapid Transit Commission?

I will not undertake to answer these questions, but it should be remembered that this Commission is composed of five men whose selection at the time made met with general commendation; that they are each men of independent fortune; each is distinguished in certain independent business lines, and all are recognized as men of public spirit, capacity and probity. They are, moreover, armed with great authority, can be safely said to be conscious of the gravity of their decision, and intent on giving to it most serious and weighty consideration.

It is then fair to accord to them an honest desire to make a determination of this question of such character as will, both in the present and in the future, prove to be undeniably the best, reserving the right of criticism both of result and motives until after the announcement of a decision which should not be unduly hurried.

Before considering the current reports of the Commission's deliberations, a general review of the subject may be advisable. There are two classes of people who are concerned in the final decision made, the public and the capitalists. In order to satisfy as far as possible the demands of both, some of which are common, it is well to examine them separately.

To accommodate the public, it is necessary to:

1st. Supply present demands by following as nearly as possible the most important existing arteries of travel. An express train on the banks of the Hudson would be of little use to Broadway.

2nd. Provide for those future lines of traffic which, other things being equal, will most naturally be formed.

3rd. Make the most numerous and convenient connections for existing and projected local and suburban transit lines in directions other than those followed by the main system.

4th. Interfere least with changes in present buildings, or the erection of future ones. In no city in the world is this change more pronounced or continuous.

5th. Cause the least disturbance to, or weakness of, foundations, present or future, and unnecessary displacement of service pipes, whether steam, gas, electric, air or sewer.

6th. Avoid disfigurement of streets and unnecessary appropriation of them.

7th. Inflict the least damage to property, either during construction or afterwards in operation.

8th. Provide the highest express and way speeds, each on independent tracks.

9th. Attain this last with the least liability of derailment or other accident.

10th. Provide the easiest access to stations, taking of all trains from one station, transfer from way to express trains and vice versa, from up to down trains, or to cross-town trains, or other intersecting lines.

11th. Finally, it must be built as quickly as possible, and should possess great flexibility.

To attract capital, the system:

1st. Should afford a reasonable and certain return on the money invested in the near, and a greater return in the remote future.

To do this the road must attract passengers, which it will do by following the main arteries of travel, and by affording increased speed, with increased comfort and safety.

2nd. Must be built economically, and as cheaply as possible consistent with sound plans for future growth.

3rd. The cost should be calculable with reasonable accuracy. This cost is comprised in a number of elements as follows:

Preparation of Way, such as tearing down buildings, digging up streets, moving pipe systems, altering sewers, sinking of shafts, etc.

Actual Construction, such as building of viaducts, erecting superstructures, driving tunnels, laying road-beds.

Temporary Damage to, and blocking of public and private business and travel during construction.

Permanant Damage to Property, whether caused by proximity to road, noise, dirt, or vibration, weakening of foundations, or interference with future buildings.

Building Space Taken Up, either by the roadway, moving trains, or necessary clearance above them.

Equipment of Rolling Stock, less with steam, greater with electricity.

4th. Should be such a construction as to make additional tracks possible, if future demands should warrant it, whether such tracks be parallel to, or intersect with, the main system.

5th. The process of construction should be hampered as little as possible by injunctions, or legal complications of any kind.

6th. The plan of construction should be such as can be most readily begun, most rapidly carried forward, and most quickly enable the road to become a dividend earner.

7th. The franchise granted should be secure from unjust restriction and future interference.

8th. The raising of capital should not be made difficult by the granting of privileges for extension to existing corporations, of such character as to make their competition in the same field. An extension of the "elevated" up the Boulevard would have its influence on any other system proposed for the same route.

That the demands of both public and capitalists as here outlined should be as far as possible met, goes without saying.

Up to very recently, from the reports of the proceedings of the public hearings which have been held, and the statements which have been made from time to time in the daily press, the Commission seems to have:

Listened publicly and with patience to all plans of routes and construction submitted for their consideration, whether good, bad or indifferent.

Selected from these plans the limited number which, during the past few years, have more or less engaged public attention, and have at least the merit of financial backing, the record of operation elsewhere, or the promise in a more or less satisfactory degree of fulfilling the demands of a rapid transit system.

Examined privately some of the representatives of some of the leading systems.

Not publicly discussed the question of motive power, but are privately investigating it, and have not yet determined what it shall be.

Expressed serious doubts as to the availability of electricity as a motive power.

Determined that, unless electricity is used, no form of tunnel, shallow, individual or deep, shall be used.

Making a personal investigation of the topography of the city with a view of determining its present needs and future lines of growth.

Determined to first lay out a West Side route.

Are attempting the coincident determination of motive power and route.

Are much concerned as to property damages.

Such, as I say, until very recently, seems to have been the attitude of the Commission.

About a week ago, however, when the public had received the impression that it had about reached a conclusion to at least a portion of its labors, application was made by the Manhattan Company for extensions covering some 18 miles of street. The character of the proposed construction, the routes demanded, are now matter of record.

---

[1] A paper read at the General Meeting of the American Institute of Electrical Engineers, May 21st, 1891.

It is but natural that the delays in submitting a route after the Chairman of the Commission had announced that it was about ready to do so, being followed by an elaborate presentation by the Manhattan Company of the plans for its proposed extension, which plans have taken a long time to prepare, preceded as this presentation was by an explicit declaration on the part of officers of this corporation that it contemplated no more extensions, naturally caused a feeling of distrust and uneasiness, and was followed by suggestions of possible bad faith on the part of the Commission, and this is no less annoying and disturbing because of its inherent improbability.

Why this action of the Manhattan Company excites this feeling is easily explained.

The portion of its scheme which most vitally concerns the city of New York is the proposed extension of the system from 33rd street up Broadway, through the Boulevard to 170th street, and its continuation. This is simply an iniquitous proposal—no other term can be applied to it, and if granted by the Commission, no matter with what restrictions, it will prove a vital blow for all real rapid transit in New York city in the life of this generation.

Let us see what will be the result of such an extension. That it would be built by the Manhattan Company if granted the right is undoubtedly true; that it would prove a profitable enterprise, is equally true; that it might be used for a repetition of the methods of financiering which characterized the consolidation of the elevated roads into the Manhattan system need not be doubted; that it will enhance the value of the property of that corporation needs no argument, but

What will it do to satisfy the needs of those who to-day use the elevated railroads?

How will it affect the well-being of this city?

With what sacrifice of its best interests would these schemes be carried out?

It is hardly necessary to point out that public spirit, civic pride or any feeling in fact, save the most sordid one, enters into the calculations of the Manhattan Corporation. Its spirit is much the same as that which prevails most unfortunately in a large portion of our city government.

It is well to recollect that some of the same men who have earned lasting condemnation of the public by their advocacy, some time since, of an elevated steel structure on Broadway, below 33d street, have again come to the front in support of the Broadway extension above 33d street.

The former scheme was for the time defeated. It has not been given up, but the basis of attack has been changed from lower to upper Broadway. Every capitalist knows the great value of a road of almost any character which can be allowed to follow this great artery of travel. Grant a franchise for the length of Broadway and the Boulevard, and there will be some interesting bidding for its control. The history of the Broadway surface road and the character of the street are in evidence. Hence, the ultimate object of this corporation is a line for the whole of Broadway.

How does it propose to get it? Defeated for a time in its assault on the lower portion, it has for months been getting the consent of property owners along the upper Boulevard, who, seeing a prospective rise in the value of their property, and careless of, or indifferent to, the real welfare of the city, and ignorant of systems save those presented by the Manhattan Company, have in many cases agreed to make no claim for damages in case an elevated structure is put up. Armed with these consents and practically assured of the consent of a city government, noted for its venality, anxious to add a heavily paying extension to its system, with lower Broadway as an objective point, and intent on defeating the raising of capital for any other system if reported, it now seeks the consent of the Rapid Transit Commission for this extension.

Consents thus sought, and in many cases obtained, ought not to weigh as an argument in favor of this extension, because the needs of the West Side property owners can be equally well served by another method of construction. That there is some explicit or tacit understanding with some of the city authorities seems evidenced by the continuance in its present disgraceful condition of the upper Boulevard, a street which was laid out for, and can be made to be, one of the finest in the world.

Let us suppose for a moment that the Commission so far prostituted its powers as to grant this extension, and it is built—What would be the result? It should be borne in mind that the traffic of the present Harlem division of the elevated road above 59th street, is mainly the growth of the past seven or eight years. It is a traffic created on account of the building which has taken place during that period. The Boulevard extension would not seriously divert travel from the present Harlem division. It would add nearly double that mileage to the present elevated system, and would build up a traffic of its own. It is safe to say, that in less than a single decade the travel on this extension would be greater than now exists on the Harlem division, while the travel on this latter would be in no wise lessened.

There would follow a congestion of traffic at, and below, 33d street, which cannot be realized, and this is precisely the result wanted by the Manhattan Company. It is impossible by any practical change in the Sixth avenue division to take care of this increased traffic, and the only outlet for it would be an extension of the road down Broadway.

Grant then the Boulevard extension for the Manhattan Company, and within 12 months after the first train has run over that extension, the necessary steps will be taken by this same corporation for the extension of the Boulevard line down Broadway from 33d street, and they will get it. There is no avoiding this conclusion.

If present public opinion will permit an extension of this system above 33d street, on Broadway and the Boulevard, for the benefit of the Manhattan Company and the West Side property owners, with the certain resulting congestion of traffic on that section of the present road, which vitally concerns all citizens, then it will in sheer desperation be compelled to acquiesce in the subsequent demand.

If to-day an intelligent and respected commission, made up of men presumably fairly representing the intelligence and public spirit of this community, cannot be relied upon to prevent the appropriation of one of the finest boulevards possessed by any city, forming the extension of one of the greatest business streets in the world, and the debauch of all real public interests by saddling upon this city the extension demanded, then it is hopeless to expect any future commission to withstand the pressure which would be put upon it.

If then it would save lower Broadway, it must protect upper Broadway. The system it adopts must be independent of, not dependent upon, the Manhattan system The rights of the West Side property owners must not be allowed to override those of the rest of the people in New York. Their interests can be better served by some other system which would give real rapid transit and leave Broadway and the Boulevard uninjured, nor should the property owners of this section be themselves content with a higher speed above 59th street, and a lower speed below 33rd.

The question is not, How can the promotors of the Manhattan system find a most remunerative opportunity for the investment of additional capital, or How can they obtain the largest return with the least expenditure? The public of New York is most concerned, possibly selfishly, with plans by which it can best serve its own interests, the real interests of a great city, one fast outgrowing the iron bound vision of the Manhattan corporation.

Fortunately it rests with any one man in this Commission to prevent any extension of the elevated system, and I think we can safely assume that no such extension will be granted except such as is consistent with the best interests of this city. I would not take the position for one moment that no rights should be granted to the elevated railway other than they now possess. I would say let its service be improved as much as is possible, but such improvement of service should not be coupled with extensions which stand as barriers to a proper solution of this problem.

If there were no other way, nor any better one, to obtain rapid transit in this city than by the system set forth by the Manhattan Company, I should say by all means let the system be thus extended, but every one within reach of my voice knows that other methods of construction can be adopted which are free from a large number of the objections which are inherent to the elevated railway system, and knowing this, we are justified in doing what lies in our power to aid in the adoption of such other methods.

In investigating the various systems it is pertinent to inquire:

When was each proposed?

How comprehensive is its character?

Which presents the most modern and progressive engineering?

Which will best satisfy the future as well as the present needs of New York city?

Which will cost least, be most quickly constructed, and hence most strongly appeal to capital?

To satisfactorily answer these queries there are three things to be determined. They are:

Motive power.

Method of construction.

Routes.

In order that the Commission may have the greatest latitude of judgment, these should be determined in the order named, that is, the determination of motive power should precede that of construction, and the method of construction that of route.

Two systems of motive power only are under consideration, steam and electricity, the former a well-known agent whose advantages and disadvantages are well known, the latter a newer application of force, one in which the layman is not so well versed, but one whose advantages and possibilities are well understood, and most thoroughly relied upon, by those who have made it their particular study.

The vital importance of letting the determination of motive power precede that of construction and route will be clearly illustrated by noting the limitations upon construction. There are five general plans which have been proposed.

A. An elevated steel structure, similar in character to the Manhattan system, and occupying the public streets.

B. The viaduct masonry construction similar to some of the London sections of English trunk line systems, the viaduct road of Berlin, or the Broad street section of the Pennsylvania railroad in Philadelphia, to run through the middle of building blocks, and to span the streets with steel arches.

C. A shallow tunnel made by excavating the streets, removing or diverting the existing system of pipe services of all kinds, running the tracks in one or two tiers, either superposed, or in different vertical planes, the street to be floored over with a steel girder structure. The enclosed track would be something like the Fourth Avenue Harlem road tunnel except that it would be entirely enclosed.

D. An iron tubular closed tunnel construction, the tubes running at a depth of from twenty to forty feet below the surface, and built something like the North River tunnel, but individualized like the Suburban and South London road constructed in London by the Greathead interests, and opened for regular service last November.

In this system the various tracks would be generally independent, and the way and express routes likewise independent save at common intersecting stations.

E. A deep rock two-track tunnel identical in character with every other rock or mining tunnel with which we are all familiar.

If electricity be adopted as a motive power, the Commission will be left untrammelled to determine which of these constructions is preferable.

If steam is adopted, considerations of construction are at once limited to plans *A* and *B*, and even then there exists a limitation in the viaduct system not yet realized, to which I will soon refer.

I think it may be taken for granted.

First, that a West Side route should come as near Broadway as possible;

Second, that a four track system is essential, because higher speed and greater capacity are required, and both way and express service must be provided.

An elevated structure necessitates the appropriation of streets already needed for other purposes. If for four tracks in one plane such a system is impossible in most of our streets. It is hardly necessary to further discuss the objection to this system.

A viaduct construction requires for every foot of way except at street crossings the condemnation and purchase of property of great value in the business heart of the city, of an aggregate far exceeding the proper cost of road construction. It means the tearing down and re-erection of many buildings, the interruption and cessation of the business carried on, with all the necessary legal complications which will surely follow, thus increasing the cost of construction in an unknown but material way, and it would require extra provision of capital for the purchase and alteration of these buildings.

But, as I have intimated, there is a distinct limitation to this plan in the simple one of motive power. There are two plans of constructing such a viaduct; one by making a clean cut through the buildings, leaving the roadway uncovered, and the other by tunneling through the buildings. If the former plan is adopted there would be thrown away a continuous strip of block space in the most valuable section of the city from twenty-five to fifty feet width, according to whether the tracks are in one or two planes, and from fifty to three hundred feet in height. Although the value of this wasted space is well-nigh incalculable, it is the only plan by which steam could be made available, because, if the roadway is covered in the block spaces and steam be used, the same objectionable features would exist which have given the Fourth Avenue Harlem tunnel so unenviable a reputation, and the damage to property would be even more pronounced. If, however, the viaduct construction were adopted, economy would demand the tunneling rather than the cutting down method of getting through buildings. This consideration would then require the abandonment of steam and the adoption of electricity.

But suppose this suggested construction and motive power be adopted in the populous portion of the city, and the street crossings be left open; there would then be that most disagreeable alternation of light and darkness, or of a greater or less degree of light, which is another of the objectionable features of the Fourth Avenue tunnel, and hence the crossings themselves must be enclosed, and with what result? The additional disfigurement of the street may be here ignored, but there would be simply an elevated tunnel of the most costly character, supported on a masonry viaduct, and a system of most questionable financial promise.

In considering an elevated or viaduct structure following the approximate route outlined, it is well to note what obstructions would be met in its course in the lower part of the city.

How, for instance, would such a system cross the Manhattan system at 34th, 53rd and 65th streets? Would a grade crossing be advisable or permissible? Unquestionably not, for the danger of collisions and the delays and blocks would at once condemn it. If not a grade crossing, then which road would be uppermost? The Manhattan being already in possession, the new system must do the crossing, and at an abnormal elevation. What would be the effect of the operation of such a road upon the Metropolitan Opera House?

As regards stations, the elevated and viaduct plans require separate up and down platforms, and it would be interesting to inquire how, with the limitations which must exist on roads of this character, it is possible to serve way and express tracks on a common level except by making them common at the way and express stations. The danger attending this practice must be apparent.

Returning again to the question of motive power, it is important to know what are the objections raised against the use of electricity. About the only one made public is that it has not yet been used on as large a scale as would be required in the proposed system. This reason seems ultra conservative, and it is to be regretted that on a subject of such vital importance, there has not been made a more thorough public inquiry.

This same view was taken of the application of electricity to street railway propulsion only three years ago. There was scarcely an engineer, a street car builder, a street railway constructor, or a capitalist, who did not laugh at the claims which were made for it, and yet in this short time there has been a total revolution of feeling. There is not, probably, a street railway manager in the United States, who does not thoroughly believe that electricity is the present and coming power for street railways, and who, if he were constructing a new road, or re-equipping an old one, would not at once, or in the near future, adopt electricity if he could get the necessary rights to do so; and it should be borne in mind that the equipping of these roads has meant, in very many cases, the entire rebuilding of the track, the purchase of new cars, the building of costly stations, and in short, the investment of a greater capital than had already been invested in the original plant, so that fifty million dollars is a small estimate of the sum which stands invested to-day, in this one industry alone.

If, however, the Commission is still in doubt, then in order to get a more intimate knowledge of what electricity can do as a motive power it would seem proper,

First: That a time be set apart for the public examination of electrical engineers and contractors.

Second: To require a private statement from electrical engineers, confidential, if desired, as to any new developments not publicly known.

Third: To visit two or three of the prominent electrical establishments to see what has been, is being, and what will be, done in general electrical machine construction.

Fourth: To then state what duty would be demanded of electric motors and what guarantees of performance would be required under forfeiture.

If something like this be not done, then I think it safe to say that the rejection of electric motive power will be because of the following reasons: Its novelty; allowing accidents incident to the early period of its developments to outweigh in importance its demonstrated advantages; a conclusion that it is limited in capacity and development, and lack of information as to its past, present, and promised future.

Such a rejection would be upon technical advice relied upon by the Commission.

This, it would seem, ought to be that of the Board of Engineers, not the judgment of any one man, because no one has sufficient experience to warrant such reliance upon his dictum in a matter of so grave import, and on a subject to which so many able engineers are devoting themselves, and the development of which has enlisted so many millions of capital.

The motor equipment on, for example, the present London road is composed of one-hundred horse-power units. That required on elevated railroads is one-hundred and eighty-five horse-power. Attach four motors of the London type to the same circuit instead of two, govern them, as is perfectly feasible, by the same controlling device, and they will outwork any elevated road engine.

Increase the dimensions in these machines one-third only, and two of them will do the work of this engine. Duality may be objected to, but it should be borne in mind that duality of engines is absolutely necessary in a locomotive for successful operation. It is not essential in an electric motor equipment, although advisable for traction purposes. But for that matter double the dimensions of a London machine, and it alone will outwork the two cylinders of the elevated locomotive.

Perhaps one of the most telling arguments in favor of electrical propulsion is the fact that in London another underground road to be operated by electricity is about to be constructed on plans already approved by a parliamentary committee. This road is about six miles long and connects the West End with the city. It forms approximately a diameter of the oval described by the present steam underground railways. A 5,000 h. p. station at the suburban end of the line will supply the current. The trains are to consist of six cars, seating about 340 persons, and will weigh with the electric locomotives 120 tons. The average speed is to be 14 miles an hour including all stops, with a maximum of about 25 miles an hour. Since this weight, power, and seating capacity exceeds that now common on the elevated railroads, it is a somewhat practical answer to the objections made on this point.

There have been no demands for a two-thousand horse-power steam locomotive, but there is not a builder in this country, who, given suitable gauge of track and allowed dimensions of engine, would hesitate a moment to build a locomotive of that capacity.

So too with electric motors. Given the incentive, and before the first foot of roadway is ready on the proposed Rapid Transit System of New York, a two-hundred horse-power electric locomotive will be built which will, under forfeiture, outwork any elevated road engine for speed, pulling capacity, steadiness of work, time of operation, and continuous mileage.

This statement is made from personal knowledge, and with an individual willingness to assume the risk.

Break a single part of the many in a locomotive and it is helpless. Break many of certain parts in an electric motor and it will, although crippled, still operate. In short, the near future will make the electric motor the most reliable machine constructed for power purposes.

What is the experience of other large cities in this matter of rapid transit?

In London the same interest which built the Greathead tunnel has been granted Parliamentary right for extensions, ordinarily most bitterly fought against, with an almost unexampled unanimity.

Paris is considering seriously the question of a great metropolitan underground electric system.

Boston has been advised after most careful investigation that the only proper system for the business portion of the city is an underground electric system.

As regards New York, while unnecessary delay is to be avoided, it is certain that no present delay is half so serious in its consequences as the adoption of an inferior plan by reason of immature consideration, lack of knowledge or information, or in response to popular clamor. The demands of to-day can be best served by plans to meet the future wants of New York as well, while the needs of the future cannot be properly provided for by planning for present limitations. In discussing the subject some time since in a communication addressed to the Commission which contained the gist of much I have already said in this paper, I made the following suggestions:

It is possible that the Commission, while still in doubt about the availability of electricity as a motive power, may feel it incumbent upon them to announce some decision with regard to at least one route. Would it not then be possible to submit two alternative propositions, the preferable one of which could be determined by public comment and criticism and the readiness with which a responsible construction company would bid for the necessary right and franchise?

First, questioning the availability of electricity, select the best system which can be devised other than an underground system, that is, some elevated or viaduct structure. Specify the number of tracks, the route over which it shall run, and make steam the motive power.

Second, accepting the statements which are made in favor of electricity, select the best underground or combined underground and viaduct and surface system, which will answer as far as possible the demands which have been enumerated. Establish the route, the number of tracks, and make the use of electricity obligatory.

Third, demand as regards: *Construction*, earliest time of beginning, greatest freedom from interference, either with streets or existing systems of pipes, least damage to property, most rapid progress of work, earliest completion. *Results*, mean and maximum speeds, number and weight of trains operated, approximate cost of motive power per train mile under these conditions. *Guarantees Under Forfeitures*, against construction damages to buildings or foundations, against future damage claims.

Then let the public discuss the merits of these alternative propositions, and let a construction company or companies bid on these systems and on the franchise, accompanying such bid with a proffer of a certified check of sufficiently large amount, and then see which company will, *a*. Guarantee to build most quickly. *b*. Make the best offer for the franchise. *c*. Offer the highest guarantees, both as to progress, cost and satisfactory operation.

As I close this paper there comes news of most reassuring character, for the chairman of the Commission is reported in Tuesday's *Commercial Advertiser* and in Wednesday's morning papers as stating in the most emphatic manner that the Commission is planning for future New York, and that it will under no consideration even consider the plans of the elevated railroad until after it has determined upon a route to satisfy the demands of that future.

This statement of the chairman is most opportune and will go far to allay the anxiety which has been honestly felt by those who await the result of the Commission's deliberation.

It is also stated, presumably on the same authority, that a system and West Side route from the Battery to the Harlem river has been definitely settled, part underground and part viaduct, and the announcement of this decision will be definitely made next Tuesday. If so, then it would seem that electricity has now the victory, and the particular method of construction and the route selected will form the subject of discussion.

MR. FRANK BICKNELL has accepted the charge of the electric light plant at the hospital, at Kankakee, Ill.

SHALL "ALUMINUM" BE "ALIUM."?[1]

BY OBERLIN SMITH.

IN February, 1890, I had the pleasure of reading before the American Institute of Mining Engineers, at their Washington meeting, a paper entitled "Aluminum in Search of a Nickname." In this essay reference is made to the fact that the nickname "Al" had already been irreverently introduced by many of the people engaged in manufacturing and selling it, in accordance, obviously, with the general tendency of our modern rapid life to condense all our commercial nomenclature into as small a compass as possible.

In accordance with this labor-saving tendency in regard to our tongues and pens, it certainly seems desirable that a shorter name than "aluminium," or even "aluminum," should be found for a metal which is destined to be so largely used in the further evolution of our modern mechanical life—and probably not a little in the electrical engineering of the future. In the paper before mentioned, reference is further made to the fact that the names of the commercial metals now in use are nearly all short, crisp, words of one syllable, as gold, tin, zinc, lead, bronze, brass and steel, while the most common two-syllabled ones, nickel, silver and copper, are also simple and easily spoken.

In further arguing the point regarding aluminum, I suggested as possible future names "Aluum," Alium," "Alim" and "Alm," as being suggestive of the original word for which they might become substitutes, and yet euphonious and easily pronounced. Since the essay in question was printed, my proposed reform has attracted considerable attention in the technical papers, the general preference appearing to be for the word "Alium" rather than for the others mentioned. This word has also been suggested independently by no less eminent a scientist than Prof. Elihu Thomson, who did not know that I had already proposed it. It has been heartily endorsed by Mr. Eugene H. Cowles, a well-known authority upon this metal, in an article in the New York *Tribune*, and by Mr. T. Commerford Martin, Past President of this Society, in the columns of THE ELECTRICAL ENGINEER.

Possibly a practical method of starting this reform would consist of one of the societies mentioned (and why not this one?) appointing a committee to distribute an argument of the case among the editors of the various technical journals, here and abroad, asking for replies as to how many of them would be willing to adopt the new word, should a majority of the whole number agree. This committee could also send communications to the other national engineering and scientific societies, requesting action, or, at any rate, an expression of opinion, upon the same subject. If each society proved willing to appoint one or more members upon a joint committee of conference, a favorable report by such a committee, especially if backed by the technical journals, would undoubtedly command sufficient respect to lead to the adoption of the name in question by the societies themselves at a later period.

If we consider the length of the names "aluminium" and "aluminum," in comparison with other elements, we find that the former is the only five-syllabled one extant. In a list of 64 elementary bodies we find only 18 of them to be words of four syllables, while 29 have three syllables, 11 two syllables, and five one syllable, the latter all happening to be ordinary commercial metals. The question naturally arises, can we afford to put a material which is probably destined to such extensive use as is this comparatively new and beautiful metal in the category of these rarely used and many syllabled elements which, as has been seen, are in a small minority of the whole number? Can we, moreover, afford to let it stand alone, in the whole list of elements, as the only one (excepting, perhaps, mercury, which foolishly has a sort of a synonym) possessing *two* distinct and interchangeable commercial names, as is now the case?

PORTLAND, ORE., INDUSTRIAL EXPOSITION.

This Association will hold its third annual exposition, from September 17th to October 17th, and are making every effort to secure a complete electrical exhibit. Secretary Mitchell says that in this they are receiving a generous co-operation from the entire Pacific Northwest.

The building will this year, for the first time, be lighted entirely by electricity, by means of 100 Thomson-Houston arc, and 600 Edison incandescent lamps.

The exposition includes general and special exhibits from the states of Oregon, Washington and Idaho. The building will be open for the reception of exhibits on and after September 1st, and applications for space and power should be made as early as possible, in order that the management may be fully prepared to meet all requirements for space and power.

The officers of the Association are:—

T. M. Richardson, president; E. A. King, vice-president; G. E. Withington, treasurer; R. W. Mitchell, secretary and superintendent.

---

[1] Abstract of a paper read at the General Meeting of the American Institute of Electrical Engineers, New York, May 21st, 1891.

THE NEW ENGLAND PORTELECTRIC COMPANY'S SYSTEM OF TRANSPORTATION.

Since the close of the exhibition of the model of the Portelectric in the "Old South Church," Boston, over a year ago, persistent and unremitting efforts have been made to determine all the conditions necessary for the construction of a commercial line for practical business purposes. Much delay has been caused in the progress of the work by the severe and uncalled-for test to which the invention was put by the contracted course which the company was compelled to adopt, and which gave little opportunity for straight runs, so essential to the development of high speed.

The present experimental track is situated at Dorchester, Mass., and the tests have been carried on under the supervision of Mr. J. T. Williams, the inventor of the system, assisted by Prof. A. E. Dolbear, the electrician of the company. In a report recently made by Mr. Franklin L Pope, we gather some interesting details as to the methods employed and the possibilities of the system.

The experimental plant at Dorchester comprises an endless track, Figs. 1 and 2, elevated upon a wooden trestle a few feet above the ground, 2,794 feet in circuit, consisting of one tangent of 492 feet, and another of 430 feet long, united at their ends by two curves, one of which is 1092 feet long and 282.5 feet radius, and the other 780 feet long and 234.4 feet radius. The track in the first tangent of 588 feet, is level, while in other portions of the circuit are grades rising to a maximum of 4½ per cent., or 227 feet per mile.

The track consists of an upper and a lower rail, formed of bar-steel ¾ inch by ¼ inch, fastened by countersunk screws to stringers. The upper stringer is of wood, 2 inches square, and the lower also of wood, 2 inches broad by 4 inches deep. The upper rail is supported and braced at intervals of about 3 feet.

The carrier, Fig. 3, is a hollow cylindrical projectile of wrought iron, with ogival ends, the cylindrical portion being 8 feet long and 10 inches in diameter, the length 12 feet over all, and the weight approximately 500 pounds. It has capacity to contain, say, 10,000 letters, weighing, perhaps, 175 pounds. It is provided with two flanged wheels above, and two underneath, all of which, being fitted with ball-bearings, revolve with very slight friction.

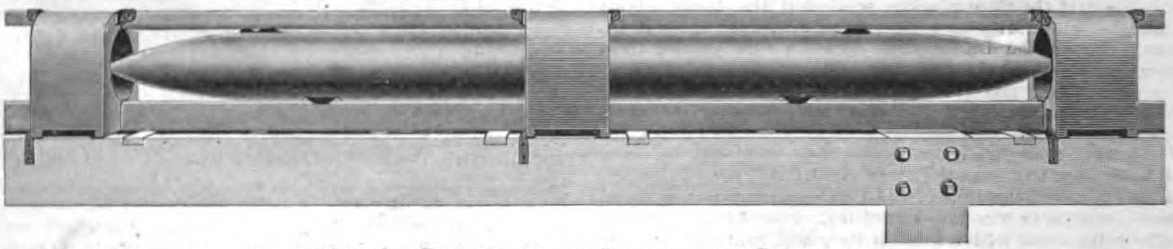

FIG. 3.—CARRIER OF THE PORTELECTRIC SYSTEM.

The propelling power is derived from a series of hollow helices of insulated copper wire, each of which encircles the track and carrier. These are fixed along the permanent way at intervals measuring 6 feet from centre to centre. Each helix is composed of 630 turns of No. 14 copper wire, in five layers, weighing about 20 pounds, and having a resistance of about 5 ohms. A contact wheel, mounted upon the carrier, and running in contact with the upper track-rail (which is divided into sections, and utilized as an electric conductor), connects the several helices in succession with the source of electricity as the carrier moves forward upon the track.

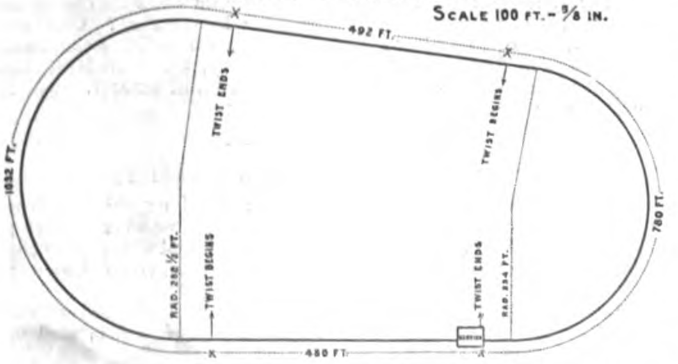

FIG. 2.—DIAGRAM OF EXPERIMENTAL PORTELECTRIC LINE.

The electric current is supplied by a dynamo having a maximum capacity of about 8,000 watts, or a little over ten horse-power, driven by a steam engine rated at ten horse-power.

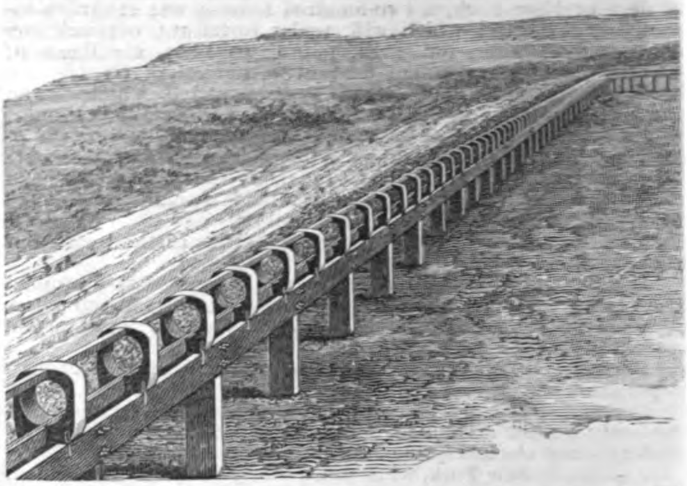

FIG. 1.—PORTELECTRIC TRACK AT DORCHESTER, MASS.

Experiments were first made to determine the maximum speed of carrier which could be obtained from the appliances in use at the time of inspection. This was found to be 2,784 feet in 56.5 seconds, or 49.3 feet per second, equal to 33.5 miles per hour.

The consumption of electric current, or rate of electric work while the carrier was in motion, was between nine and ten electric horse-power. The maximum tractive effort with a current of ten amperes was found to be 80 pounds. The electrical force producing this magnetic attraction was 6,300 ampere-turns.

The rate of acceleration was found to be as high as 4.5 feet per second. The force of traction required to produce this acceleration, with the carrier of 500 pounds' weight, is about 70 pounds.

A tractive effort of 70 pounds, exerted upon the carrier moving at the rate of 50 feet per second, requires the expenditure of 6.3 horse-power, or 4,712 watts. As the average electrical energy supplied appeared to represent something like 8,000 watts, the efficiency of the helices and carrier, considered as an electric motor, may be estimated at about 60 per cent., which figure agrees very well with other determinations of solenoid magnets.

There are eight hundred and eighty helices, and seventeen thousand six hundred pounds of insulated wire per mile in the helices, in addition to that in the main conductors.

As each coil is ordinarily in circuit for only a fraction of a second at a time, it is evident that a volume of current per unit of sectional area may be used with impunity in this case, which would be wholly inadmissible under ordinary conditions.

The provision for power required to propel the carrier at the assumed rate of 150 miles per hour, may be taken at fifteen hundred volts and seven amperes per forty miles of single track, or about 0.33 horse-power of *generating capacity* per mile. This may be estimated, including steam plant and buildings, at $125 per horse-power, or, say, $45 per mile.

The actual cost of the electric power required to propel the carrier at this rate may fairly be taken at five cents per horse-power hour, including cost of attendance at stations. The mere cost of *power* for propelling a carrier from Boston to New York would therefore not exceed seventy-five cents per trip.

Excessive estimates of the cost of a double-track line, making liberal allowances in all directions, do not exceed $35,000 per mile, or about $7,000,000 for a line between Boston and New York.

THE ELECTRIC CLUB'S RECEPTION TO THE INSTITUTE.

A VERY pleasant and memorable evening was spent at the house of the Electric Club on Thursday evening, by the members of the Institute, about 400 or 500 gentlemen connected with electrical pursuits being present at the reception tendered by the club to that body. The reception was of a wholly informal and social nature, but was made specially interesting by the Loan Collection of early electrical books, apparatus, autographs, etc., got together by the Entertainment Committee of the Club and arranged in the Lecture Room and Library. This exhibition comprised about 150 rare and important electrical books, from the collection of Park Benjamin, and so arranged in groups that each case, by means of these volumes and their contents, told the story of the period at which they were written. The first case, for example, contained Diogenes Laertius, Agricola on Metals, Gilbert's De Magnete, and many of the works spoken of by Dr. Gilbert. These books were grouped as "The Dawn of Electricity." Among the rarities and curios of the collection were James Watt's French Grammar, with his autograph and the date 1752 in his handwriting; an early electrical book with Benedict Arnold's autograph; the early Galvani and Volta treatises, and five of Ampere's papers, with autograph, and a letter of Arago. This collection, which is but a small part of Mr. Benjamin's collection, was studied with the greatest interest. The exhibit also contained Mr. Edward Weston's copy of De Magnete; Dr. Lugo's copy; and that of Mr. C. L. Clarke, with Gilbert's autograph presentation of it to Jo. Sherwood on the title page. Among the miscellaneous collection contributed to by Messrs. Edison, Weston, Clarke, Webb, Wetzler, F. L. Pope, Barré, Hammer, Martin, Chandler and others, were early books on electricity, relics of the early telegraph and cable days, a number of autographs, etc. The *Century* Co. loaned a piece of the wire used by Morse and Vail in 1838, and the University of the City of New York loaned the first battery used by Morse.

The collection of early apparatus included one of Ezra Cornell's insulators from Mr. F. L. Pope; Mr. Wm. Stanley's first transformer, 1885–6; the Davenport electric railway of 1835–7; an Edison hedgehog transformer of 1878, used to run 20 of his platinum lamps; a fine collection from Mr. E. F. Gennert illustrating "The Evolution of the Socket;" a selection from Mr. W. J. Hammer's magnificent collection of incandescent lamps, as well as his rare books, photographs, autograph portraits, etc.; and the first chandelier ever wired for incandescent lighting, from the collection of Mr. Luther Stieringer, who also loaned some of his curiosities of the early incandescent art. Around the Lecture Room were hung a selection from Mr. Edward Weston's fine collection of autograph portraits, and the mantelpieces were also graced with pictures, including two oils illustrative of submarine cable work, by Mr. H. D. Gardiner, loaned by *Scribner's Magazine.*

In the Library were shown some interesting early autograph letters, etc., of Morse and Henry, and a portion of the very interesting War Collection of Mr. A. B. Chandler, who, as a young telegrapher, did duty with Stanton and Lincoln. The collection contained very interesting autograph papers of those two great men, as well as of McClellan, Spinner, Bingham, Seward, Barnum, Morse, Edison, Orton and others, as well as such curiosities as Confederate telegraph register paper, war telegraph ciphers, etc.

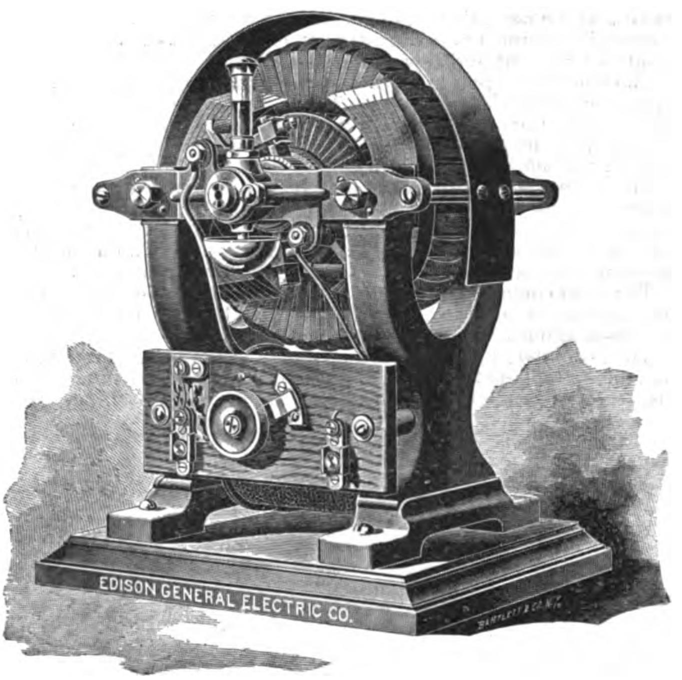
During the evening a collation was served, and music was played by the Bridgeport Mandolin band. Before the evening closed, President Insull expressed, in a few happy remarks, the pleasure felt by the Club in thus entertaining the Institute, and the hope that the alliance would be made even more friendly and cordial, for the furtherance of their common interests and the promotion of electrical welfare. The compliment was acknowledged in behalf of the Institute in a most eloquent speech by Mr. Edward Weston, who, like Mr. Insull, spoke as a member of both organizations. Mr. Joseph Howard spoke for the press, and Prof. George Forbes replied for the electricians from abroad. The announcement was then made that a talk would be given at the Club on Thursday evening, May 28, on "The Tools of Modern Warfare," by the distinguished inventor and pioneer electrician, Mr. Hiram Maxim, who had been one of the guests of the evening. Thus closed one of the most enjoyable and successful of the many notable "Nights at the Club."

THE SERVICES OF GEN. ELECTRICITY.

In a retrospect of the Civil War, John C. Ropes, an acknowledged authority on military science, says, in the June *Scribner*, that steam and electricity made possible for Grant and McClellan what had been impossible for a Napoleon. Otherwise the predictions of Palmerston and Napoleon III., that the North would fail, would probably have been fulfilled.

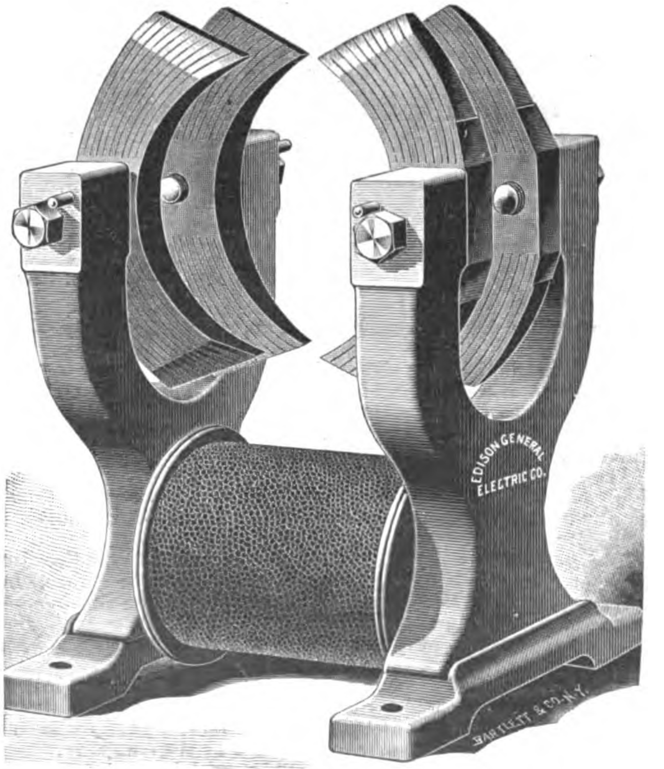
SMALL EDISON SLOW SPEED MOTORS (1891 TYPE).

THE uses for small motors, that is, from $\frac{1}{16}$ of a horse-power to ½ horse-power, inclusive, are surprisingly numerous. Work formerly performed by hand is now, for the first time, done by power; and every day some new application of the small electric motor is made. Recognizing this fact, Mr. Edison has designed a motor with special reference to its use in small sizes, in which he has embodied the features of minimum of attention and repair, high efficiency, small first cost, slow speed, and perfection of mechanical detail.



EDISON GENERAL ELECTRIC CO.
BARTLETT & CO. N.Y.

FIG. 1.—EDISON SMALL MOTOR.



EDISON GENERAL ELECTRIC CO.
BARTLETT & CO. N.Y.

FIG. 2.—FIELD OF EDISON SMALL MOTOR.

The motor has been so designed that no adjustment of the brushes whatever is required, the brush holders being fixed in position and requiring no attention after being once adjusted. Lubrication being accomplished by the use of grease instead of oil, very little attention is needed in that particular.

By connecting the coils of the armature with the commutator by German silver wires, the sparking which has heretofore been found so objectionable in small machines is entirely eliminated. This is a feature which will be at once appreciated by power users. As each coil of the armature is wound independently of the others, any coil can be replaced with the greatest ease.

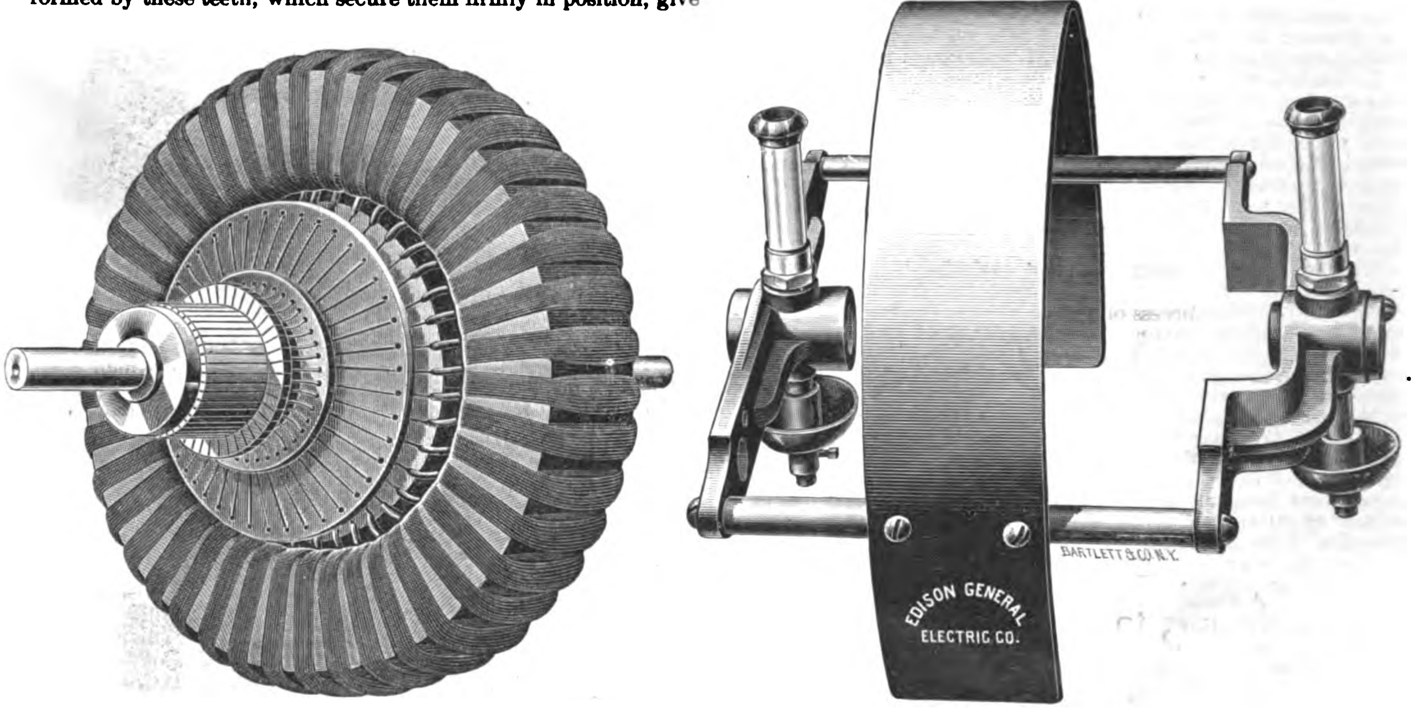
The bearings of the armature shaft consist of removable brass sleeves, which are adjusted to permit of perfect alignment. Upon the wearing of the brass bearings by continued use, they can be readily slipped out and new ones substituted in a few minutes.

The general arrangement of the motor is shown in Fig. 1 of the accompanying illustrations. The armature revolves in a magnetic field, the lines of force being brought through the armature on both sides of the ring by means of specially shaped pole pieces made of the softest Norway iron.

The poles, shown in Fig. 2, being built in strips, secure a lamination which prevents the heating of the fields, thus permitting the motor to run cool even when overloaded. These wrought iron pieces are attached to the magnetic frame, which at the same time forms the base upon which the machine is mounted.

The single field magnet coil is placed below the armature. This brings the centre of gravity low, and hence adds to the steadiness and solidity of the machine.

The armature, Fig. 3, is built of the softest laminated wrought iron, and is provided with teeth. The coils are placed in hollows formed by these teeth, which secure them firmly in position, give them a positive driving arrangement, and prevent slipping of the coils.



BARTLETT & CO. N.Y.
EDISON GENERAL ELECTRIC CO.

FIGS. 3 AND 4.—EDISON SMALL MOTOR ARMATURE AND GUARD.

This construction also allows the projecting teeth to be brought in the closest possible proximity to the pole pieces, so that the field magnets can be brought very close, lessening the air gap, without the slightest danger of abrading the winding of the armature.

These motors have been designed to meet the demand for a highly efficient machine which would be at the same time of low cost, by the adoption of a type employing the smallest number of parts with the lowest possible weight of material.

The great desirability of slow speed in the operation of the electric motor is recognized by the Edison General Electric Company, as this reduction results in a great saving in the wear of commutator, bearings and brushes, and admits of the application of these machines to purposes where the use of motors has heretofore been impractical.

The details of the mechanical construction of the new Edison motor have been as carefully considered as the electrical features, and both material and workmanship have received the same care and attention as the largest machine built by the company.

The armature of the motor is provided with a guard, shown in Fig. 4, which protects it from accidental injury, and also forms a partial cover for the machine.

All parts of the motor are made interchangeable so that new parts can be fitted without trouble.

The machines are equipped with a mahogany switch-board upon which are mounted the terminals for making circuit connection, and also a strong and simple switch, together with a safety fuse for protecting the motor from excessive current.

This type of machine is built in sizes from $\frac{1}{16}$ to $\frac{1}{2}$ h. p. The following table gives the various speeds, currents and weights.

Type in h. p.	Volts.	Amp.	Speed.	Weight.
$\frac{1}{16}$	125	.4	2200	$14\frac{3}{4}$
$\frac{1}{8}$	125	.8	2000	$20\frac{1}{4}$
$\frac{1}{4}$	125	1.6	1300	$28\frac{1}{2}$
$\frac{1}{2}$	125	3.2	1500	$37\frac{5}{8}$

It will be noticed that the weights of these motors are very low.

ANNUAL MEETING OF THE AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

THE annual meeting of the Institute was held at its headquarters, 12 West 31st street, on May 19, at 8 P. M., President W. A. Anthony in the chair.

Secretary R. W. Pope presented the annual report of Council. It showed a total effective membership of 541, a net gain of 114 during the year. The secretary's balance sheet showed $5,727.96 received; and the disbursements of the year, taking into account the balance over from last year, showed a balance in hand of $752. During the evening $500 was voted out of the balance toward the building fund, for which Messrs. Phelps and R. W. Pope were appointed trustees.

Prof. Anthony appointed Messrs. F. L. Pope, T. C. Martin and J. W. Howell as a nominating committee. The report of the committee was accepted, and the nominations were made with unanimity. Subjoined is the full list of officers, the new members being indicated in italic and the re-elections in small caps.

PRESIDENT. *Alexander Graham Bell.*

VICE-PRESIDENTS. *T. D. Lockwood, Carl Hering, W. J. Hammer*, Prof. F. B. Crocker, F. J. Sprague, Joseph Wetzler.

MANAGERS. *Dr. Louis Bell, H. L. Webb, Prof. A. G. Compton, J. Hamblet*, Dr. F. B. Herzog, Dr. W. E. Geyer, H. C. Townsend, F. R. Upton, J. C. Chamberlain, P. B. Delany, H. A. Foster, H. W. Leonard.

SECRETARY. R. W. Pope.

TREASURER. G. M. Phelps.

The meeting discussed a few matters of detail and routine, and then adjourned to the Edison station in West Twenty-Sixth street, which was carefully inspected.

At the morning session of Wednesday, Prof. Crocker read a paper on "The Perfection of the Stationary Electric Motor," which was followed by one by Prof. Hall, of Harvard, on electrical tests of cylinder condensation.

After the adjournment for lunch, Prof. E. L. Nichols, of Cornell University, read a paper entitled "Some Data Concerning the Photometry of the Arc Lamp;" Mr. Carl Hering, one on "A New Graphical Method of Calculating Leads for Wiring;" and Dr. F. A. C. Perrine, one on "Some Results in the Practical Utilization of Electric Welding.

The evening was given up to a lecture by Mr. Nikola Tesla, at Columbia College, on "Experiments with Alternating Currents of High Frequency." This was largely attended, as on previous like occasions, Dr. Dwight's room being filled to overflowing, the audience including a great many ladies. The lecture was profusely illustrated by experiments.

On Thursday morning the members met first at the Crocker-Wheeler Motor Factory, and a large number inspected it with much interest. Afterwards at headquarters papers were read by Prof. Geo. S. Moler. on "A New Device for the Measurement of Alternating Current Potential;" by Mr. M. E. Thompson on "A Study of the Fluctuations of Electromotive Force in the Open Coil Armature of a Constant Current Machine," and Mr. Frank J. Sprague, on the considerations which should determine the Rapid Transit System in New York city.

After lunch, a paper was read by Mr. G. W. Walker on "Electric Meters" with illustrative experiments, and Dr. W. H. Wahl, delivered an address on "The Aluminum Problem: Retrospective and Prospective." This was accompanied by a most interesting exhibit of the aluminum products of the Pittsburgh Reduction Co., and the alloy products of the Aluminum Brass & Bronze Co. of Bridgeport. Mr. Oberlin Smith also read a paper entitled: "Shall Aluminum be Alium?"

The chair also was given power to appoint delegates to represent the Institute at the Frankfort Exhibition Electrical Congress.

The discussions on these papers were remarkably lively and good, and were participated in freely by Profs. Elihu Thomson, Anthony, Crocker, Nichols, Geyer, George Forbes, Messrs. Weston, F. L. Pope, Wheeler, Lockwood, Bell, Sprague, Waldo, Mailloux, Sweet, Rice, and many others.

The meeting closed on Thursday evening with the reception tendered to the Institute by the Electric Club, at the Club House.

A large part of the success of the meeting is due to the efforts of the local committee, comprising Messrs H. A. Foster, chairman, Binney, Reid, Caldwell and Lieut. Ives. A special badge provided by the committee in the shape of a horseshoe magnet, made out of aluminum, with the letters A. I. E. E., and with 1884-91 on the keeper, proved very popular. A word of praise is also due to Mr. W. W. Stadler, the steward of the Electric Club, whose services were placed at the disposal of the Institute, with the result that the collation each day was perfect in every respect.

A large crayon portrait of Prof. Anthony, the retiring president, has been presented to the Institute, and now hangs on the walls of the meeting hall.

Letters to the Editor.

A CORRECTION.

I find certain errors in the table of formulæ accompanying my paper read at Montreal, and printed in THE ELECTRICAL ENGINEER of May 13, which errors are typographical ones made at this office. Will you kindly make the following corrections:

1. In the formula for Power at Motor Pulley, which reads

$$M = \frac{D \times \text{h. p.} \times 1,600}{V \times e \times P},$$

the number 1,600 in the numerator should be 16,000.

2. In the formula of Weights For Any Case, which is

$$T = \frac{C \times D^2}{V \times 746.0},$$

the decimal point following the 6 should be struck out, and the figure read 7,460.

In the definition of *G*, read "delivered *to* conductor" instead of "delivered *by* conductor."

H. WARD LEONARD.

Edison General Electric Co., N. Y. City.

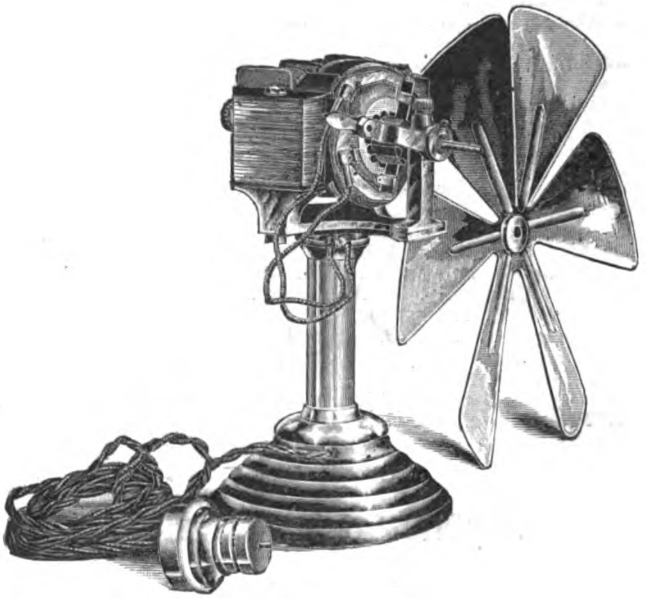
AN OPPORTUNITY AT CORTLAND, N. Y.

The Hitchcock Mfg. Co. being about to move its wood working plant to the South, desires to find a purchaser for its electric light plant as a going concern. The plant consists of arc and incandescent apparatus, and the city now calls for a considerable increase in the lighting. With the plant goes a franchise and a contract for lighting the city of Cortland for ten years, of which only about two have expired.

THE NEW WESTINGHOUSE FAN MOTOR.

THE Westinghouse Electric and Manufacturing Co. are constructing fan motors which they believe to embody all the salient points required in an economical and perfect ventilator. The device has been very thoroughly tested and it has proved to have many advantages. It can be successfully used on an alternating incandescent circuit. Attached to any ordinary lamp socket, it will not use more current than one lamp. One of the motors was placed in one of the company's offices last November, where it has been running without interruption for six months. During all this time, it has required no attention whatever, not even the application of a lubricant being necessary.

The armature coils and the wires leading from the armature to the commutator are completely imbedded in a cementing material. This method of imbedding the delicate parts of the apparatus precludes all danger of short-circuiting and it obviates any breaking of the wires by rough handling.



WESTINGHOUSE FAN MOTOR.

The speed of the Westinghouse fan motor can be varied in a manner so simple that even a child may be entrusted with doing it. The motor has two carbon brushes, which are set so as to work automatically; at the same time, they need not be renewed for years. A moving of these brushes to the left or the right causes the armature either to revolve fast or slowly. Apart from the usefulness of this little apparatus, it is highly ornamental. The fan is nickel-plated and the stand on which it is mounted is of brass. The fan motor can be carried about to any part of the room, as it only weighs about nine pounds.

Legal Notes.

THE GREAT WESTERN TELEGRAPH CO.

Master in Chancery Boyerson filed his report in the Circuit Court at Chicago, on May 2, in the celebrated case of ex-United States Senator Charles B. Farwell against the Great Western Telegraph Company to set aside the claims of Selah Reeve, the Commercial National Bank, George F. Harding, and John Clark Hilton, and to vacate an assessment of 35 per cent. against 1,200 stockholders of the company to meet an alleged indebtedness of $350,000. This assessment, it was charged, was void because of the fraudulent claims allowed against the estate.

The Master recommends that the decree of assessment be set aside, which relieves the stockholders; that the claims of Selah Reeve and Thomas J. Sutherland against the estate be expunged as invalid; that George F. Harding be compelled to account for some $60,000 alleged to have been received by him in excess of the amount of his claims; that Sutherland be obliged to account for the claims held by him against the company, and that a perpetual decree be entered against Sutherland, Harding, Franklin, and Gray for the amount received by them from the sale of the lines of the company. The Master finds that the decree of assessment was procured by fraud.

Society and Club Notes.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

At the meeting of the council held May 19, the following applications for associate membership were voted upon favorably:

Alden, James S., Assistant Manager, with L. H. Alden, 486 River Drive, Passaic, N. J.
Ayer, James I., General Manager, Municipal Electric L. & P. Co., 322 Pine St., St. Louis, Mo.
Bowman, Fred. A., Electrical Engineer, N. Y. Isolated Dept., Thomson-Houston Electric Co., 65 Columbia Heights, Brooklyn, N. Y.
Colville, Frank C., Electrician and Inventor, 1503 Seventh ave., Oakland, Cal.
Essick, Samuel V., Electrician, The Essick Printing Tel. Co., Yonkers, N. Y., 171 Broadway, New York City.
Everest, Augustine R., Electrical Expert, Thomson Electric Welding Co., Astor House, New York City.
Hancock, L. M., Supt. of Construction, Western Electric Co., 22 Thames St., New York City.
Hewlett, Edward M., Electrical Engineer, Isolated Dept., Thomson-Houston Electric Co., 65 Columbia Heights, Brooklyn, N. Y.
Mason, James H., Electrician and Supt. Mason Battery and Electrical Co., 120 Park ave., Brooklyn, N. Y.
Smith, Oberlin, President and Mechanical Engineer, Ferracute Machine Co., Lochwold, Bridgeton, N. J.
Squier, George O., Lieut. U. S. A., Student of Physics, Johns Hopkins University, Baltimore, Md., Box 243.
Stone, Charles A., Manager with E. S. Webster, Mass. Electrical Engineering Co., 4 P. O. Square Boston, Mass.
Uehling, F. A., Ass't. Supt. and Chemist, U. S. Aluminum Metal Co., Boonton, N. J.
Wason, Chas. W., Electrical Engineer, East Cleveland R. R. Co., 1762 Euclid ave., Cleveland, O.

Reports of Companies.

SCOTT ELECTRIC MANUFACTURING CO.

The annual meeting of the stockholders of the Scott Electrical Manufacturing Company was held at the office of the company, No. 1 Exchange Place, Jersey City, May 15th, and the following Board of Directors elected:—J. G. Scott, B. H. Herbert, E. M. Brown, J. Earl Brown and Richard Deming. President and general manager, J. G. Scott; treasurer, Thomas I. McCloud; secretary, B. H. Herbert,

THE ELECTRIC MUTUAL INS. CO. has just issued some very interesting data and circulars regarding its praiseworthy work. Its rate of premium on acceptable risks averages about one per cent. per annum, and dividends, by reason of its scientific and business-like methods, and which will be paid at termination of each policy, are expected to materially reduce that rate. The company received its charter in May, 1890, and issued its first policy on the 15th of that month. The first eleven and one-half months have yielded over $47,000 in premiums. Although the expenses incident to the first year have necessarily been large, the company has declared a twenty per cent. dividend payable on premiums expiring in May, 1891, and added an equal amount to reserve. Each policy participates in the success of the twelve months preceding the date of expiration of the policy; *i. e.* the premiums, interest and other items of income for the preceding twelve months are added together, and from that sum is deducted the aggregate sum of losses and expense for the same period.

DIVIDENDS.

FAIRFIELD, ME.—The Electric Light Co. has declared a semi-annual dividend of 3 per cent.

THE EUREKA TEMPERED COPPER CO., of North East, Pa., report that their largely increasing business has necessitated the enlarging of their plant, and they are now laying the foundation for a new moulding room 50 x 140 feet, hoping that the increased facilities which this addition will afford, may enable them to meet the increasing demand for their tempered copper.

Appointments, Etc.

MR. C. C. UPHAM has resigned his position as manager of the Salt Lake Rapid Transit Co. and has been appointed manager of the Lincoln City Street Railway Co., of Lincoln, Neb.

MR. C. H. STICKLES, who has been secretary of the Snohomish, Wash., Electric Light Company ever since its organization, and for two years its general business manager, has resigned his position with that company, and has accepted a position with the Edison company to take charge of their work at Portland, Ore.

MR. E. A. SWEET, of Milford, Mass., has accepted a position as electrician and manager of an electric light company in Augusta, Ga.

MR. W. A. RUDD has taken charge of the Western Union telegraph office, at Marquette, Mich., and Mr. L. S. Humes has gone to Supt. McMichael's office, at Minneapolis.

MR. S. DANA GREENE has been appointed consulting electrician to the Burton Electric Co., of Chicago, who control the Burton heater, with which Mr. Greene conducted some of the earliest experiments in street car heating by electricity. The appointment will not in any way interfere with Mr. Greene's work as assistant to the second vice-president of the Edison General Electric Co.

MR. S. ASHTON HAND, of Phila., a widely-known mechanical engineer, member of the American Society Mechanical Engineers, and lately general superintendent for Morris, Tasker & Co., has joined the forces of the Equitable Engineering & Construction Co. Mr. Hand will take entire charge of the mechanical engineering department of the Equitable Co., whose offices are in the Drexel Building, Philadelphia.

MR. H. E. ALLEN, who has been manager of the Central Union Telephone Exchange at Sandusky. has been transferred to the exchange at Canton, O.

MR. WALTON STORM, a lawyer of this city and a graduate of the Columbia College Law School, has been appointed by Gov. Hill to fill the vacancy as commissioner on the New York Board of Electrical Control. He has already been sworn in.

Obituary.

WELLS W. LEGGETT.

The death is announced of this well-known patent lawyer. He was president of the Detroit Brush Electric Light Co., and was also prominently interested in a number of other large enterprises. Mr. Leggett was born in 1847 at Farmington, O., and after war service, etc., began the practice of patent law in 1872.

Stock Quotations.

QUOTATIONS ON ELECTRICAL STOCKS.

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED MAY 19, 1891.

Alarms and Signals :—

Electric Push Button, M. Straus, 452,397. Filed Oct. 4, 1890.
Details of construction.

Electric Signal Apparatus for Fire Hose, J. F. Klumpp, Jr., 452,506. Filed May 17, 1890.
For communication between a hoseman and the engineer of a steam fire-engine.

Annunciator Drop, H. C. Shivler, 452,585. Filed Feb. 11, 1891.
Details of construction.

Electric Alarm, C. H. Shaffer, 452,785. Filed May 5, 1890.
A closed-circuit alarm system.

Clocks :—

Self-Winding Clock, F. M. Schmidt, 452,392. Filed Nov. 25, 1890.
Employs a small reciprocating motor.

Electric Synchronizing Device for Clock-Hands, A. M. Church, 452,424. Filed Nov. 18, 1889.
Electro-mechanical devices for synchronizing a number of clocks automatically from a standard clock.

Conductors, Conduits and Insulators :—

Insulated Electric Conductor, J. B. Williams, 452,510. Filed Nov. 12, 1890.
Consists, principally, in interposing air spaces between the dielectric and the conductor.

Joint for Electric Conductors, E. Carroll and T. B. Lambert, 452,516. Filed Nov. 18, 1890.
The ends of a conductor are firmly secured and held apart in an insulating block or holder provided with a removable contact piece or plug.

Glass Covered Electric Wire, W. Curry, 452,565. Filed Mar. 5, 1891.
Consists in covering the wire with glass insulators made in tubular sections fitting against each other, each section comprising two parts fitting together and bound upon the conductor by a flexible wire in a peripheral groove.

Insulated Electric Conductor, J. B. Williams, 452,725. Filed Nov. 12, 1890.
Employs isolated or non-communicating air spaces between the dielectric and the conductor.

Composition of Matter for Insulating Purposes, F. Salathe, 452,760. Filed Nov. 12, 1890.
Employs a resinoid hydrocarbon together with sulphur, or with india rubber, gutta percha or oxidized linseed oil.

Composition of Matter for Insulating Purposes, F. Salathe, 452,765. Filed Apr. 22, 1891.
Claims the combination of gutta percha and gum shellac with the new hydrocarbon product of No. 452,760, above.

Dynamos and Motors :—

Dynamo Electric Machine or Motor, F. A. Wessel, 452,420. Filed Nov. 19, 1890.
Relates especially to the arrangement and construction of the cores of field magnets.

Electric Switching Apparatus, G. T. Briggs, 452,359. Filed Apr. 7, 1890.
An adjustable rheostatic switch adapted for reversing and controlling electric motors. Especially applicable for use in hoisting and other operations requiring complete and prompt stopping.

Rheostat, C. D. Jenney, 452,574. Filed June 14, 1890.
An adjustable rheostat for use with dynamos and motors.

Electric Motor, E. Gray, 452,429. Filed July 3, 1888.
Relates to a motor especially adapted for use with the receiving pen of a telautograph system ; operated by impulses and produces a step by step movement.

Brush Holder for Commutators, I. H. Bartholomew, 452,561. Filed Jan. 19, 1891.
Details of a spring-actuated brush carrier.

Bipolar Dynamo or Motor, A. L. Riker, 452,718. Filed Feb. 18, 1891.
Relates to the construction of the continuous frames forming the poles and pole pieces of field magnets.

Lamps and Appurtenances :—

Electric Light Fixture, J. G. Fischer, 452,367. Filed Sept. 8, 1890.
A cut-out for electric lamps.

Leading-in Wire for Incandescent Electric Lamps, R. A. Fessenden, 452,494. Filed Feb. 18, 1891.
Consists of silicon alloyed with a metal having a higher coefficient of expansion than glass.

Electric Arc Lamp, F. Buchanan, 452,633. Filed Jan. 9, 1891.
Relates to feeding mechanism and provides for feeding either or both carbons.

Sectional Shade for Incandescent Electric Lights, A. F. Gartner & J. C. Harris, 452,638. Filed Aug. 30, 1890.

Shade for Incandescent Electric Lights, A. F. Gartner & J. C. Harris, 452,701. Filed Aug. 30, 1890.

Miscellaneous :—

Luminous Sign, C. Beck, 452,514. Filed Dec. 15, 1890.

Explosive Engine, A. Harding, 452,520. Filed Dec. 10, 1890.
Employs electricity for ignition.

Wind Apparatus for Generating Electricity and Charging Secondary Batteries, J. M. Mitchell, 452,546. Filed Dec. 15, 1890.
Combination of a windmill with a dynamo and storage batteries.

Electric Device for Harness, A. B. Holson, 452,571. Filed Oct. 6, 1890.
Substitutes an electric shock for the spur or whip.

Machine for Molding Carbon Points, T. B. Dooley, 452,599. Filed Sept. 15, 1890.

Railways and Appliances :—

Controlling Device for Electric Motors, F. O. Blackwell, 452,422. Filed July 13, 1889.
Claim 1 follows :
The combination of an electric motor having a sectional field and a variable resistance, by both of which agencies the motor is regulated, and a switch independent of the resistance-controller for cutting out or short circuiting a section of the field.
Applicable to electric railway motors.

Controlling Device for Electric Motors, F. O. Blackwell, 452,423. Filed July 13, 1889.
Combines in an electric car a resistance located at an intermediate point, two sets of connections extending to separate points of the car and there terminating in duplicate sets of contacts provided with contact arms and reversing devices.

Electric Railway Train Signal and Recorder, F. H. Brown, 452,515. Filed Dec. 3, 1890.
A system of circuits and apparatus for indicating the position and progress of a train to the operator in the train dispatcher's office.

Electric Insulator, B. Jennings, 452,523. Filed Sept 12, 1890.
A supporting insulator for trolley wires.

Trolley Device for Electric Railways, D. N. Cook, 452,542. Filed July 18, 1890.
A trolley carrier with flexible support.

Crossing for Overhead Trolley Wires, J. Kuehnle, 452,576. Filed Jan. 2, 1891.
Consists of a metallic spider formed of two or more parts crossing each other, and depending interlocking means rigid on the spider, holding the parts together and adapted to engage between the flanges of the trolley.

Conductor for Electric Railways, E. W. Mitchell, 452,611. Filed Feb. 5, 1891.
The conductor extends within an insulated tube or covering, the latter having contact pieces at suitable distances apart throughout its length, normally out of contact with the conductor but adapted to make contact under pressure from a trolley wheel.

Motor Mounting of Electric Cars, S. H. Short, 452,621. Filed Nov. 15, 1890.
Comprises an axially-mounted and directly-connected armature carried upon and cushioned from a driving axle, and non-rotative field-magnets bearing upon the armature axles ; roller bearings are interposed.

Electric Railway Car, S. H. Short, 452,622. Filed Dec. 17, 1890.
A directly applied motor is mounted in journal bearings formed in the yokes of the field-magnets.

Insulator Holder for Electric Railways, B. Jennings, 452,645. Filed Nov. 5, 1890.

Electric Motor or Generator, A. L. Riker, 452,717. Filed Feb. 18, 1891.
Has special reference to the assembling of the laminated frames of the field magnets. Especially applicable to railway motors.

Electric Railway System, D. G. Weems, 452,741. Filed March 13, 1890.
Improvements upon the systems previously patented to the same inventor. Designed to reduce to a minimum the fractional resistance of the air, and to provide convenient means for lubricating moving parts.

Telephones and Apparatus :—

Telephone Transmitter, P. Fitzsimmons, 452,636. Filed Dec. 23, 1890.
Details of a microphone.

Microphone, A. C. F. Muller, 452,758. Filed May 31, 1889.
Employs a rolling electrode.

NEW YORK NOTES.

THE ENGINEERING EQUIPMENT CO., Central Building, Liberty St., N. Y., are making a specialty of the Kellogg iron pole, which they find to be just the thing, and a great favorite among electric railroad men.

THE MURPHY SLATE.—In a recent letter to Mr. T. J. Murphy, 96 Columbus Ave., N. Y., the National Electric Mfg. Co., of Eau Claire, Wis., say : "We use slate for the following purposes : Dynamo switchboards, switchbases, bases for transformer fuses—in short, wherever we formerly used fibre or hard rubber. We know of nothing at present which would answer our purpose as well as your slate, all things considered." Mr. Murphy is beginning to enjoy a large trade as the result of a growing appreciation of the desirable insulating qualities of his special slate.

THE INTERIOR CONDUIT & INSULATION CO., through Mr. H. M. Underwood, their Chicago agent, have secured the contract for the conduiting and wiring for arc and incandescent light, of the Fourteenth street pumping station, of the city of Chicago.

THE CRESCENT INSULATED WIRE COMPANY, of Trenton, N. J., in a recent letter received at this office, say they expect to be running their factory in a few days. They will turn out a superior rubber insulated wire, and no doubt will find a ready market for their goods.

MR. J. STANFORD BROWN, the well-known electrical engineer, who has been connected several years back with electric railway enterprises, has taken an office in the Electrical Exchange Building as a consulting engineer. Mr. Brown is one of the pioneers in the electric light as well as the railway business, and any person contemplating the erection of any kind of an electrical installation will find his services very valuable.

THE MCLEAN ENGINEERING COMPANY, consulting and contracting engineers for steam and electric plants and all work of this character, have taken an office in the Electrical Exchange Building, 136 Liberty street, where they will be found ready for business.

THE STANDARD PAINT COMPANY have removed their offices from 59 Maiden Lane to 2 Liberty street, where they will be glad to meet all their old friends and customers. The well-known trade mark "P. & B." is painted on the front of the store in a prominent manner so there will be no mistaking their location to any one happening in that vicinity.

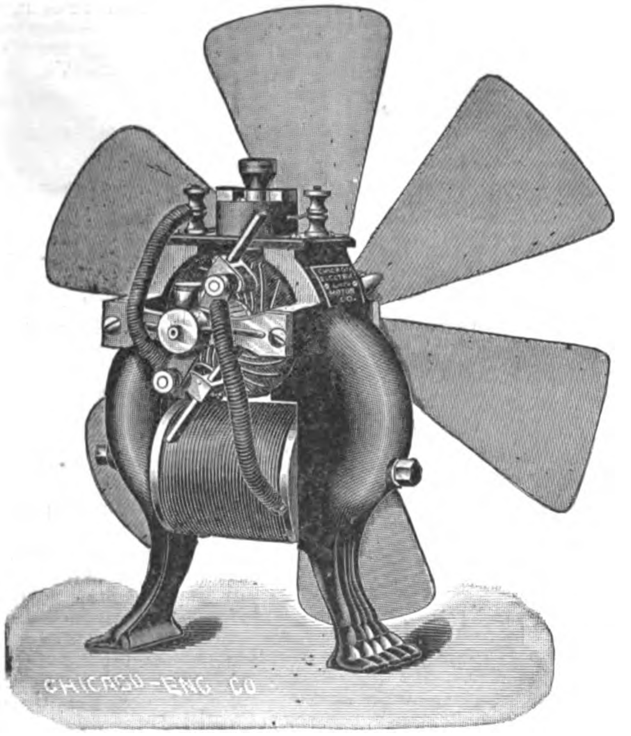
TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

The successful advertiser sets people thinking, talking—and buying.

THE CHICAGO FAN MOTOR.

ONE of the latest and handsomest little fan motors brought out, is shown in the accompanying illustration, which represents a 1/6 h. p. machine. A modified Gramme ring armature of the most efficient form is employed, and it is made of specially strong and durable construction, the conductors being insulated from the core and from one another in the most thorough manner, rendering a burn-out impossible. The field magnet core is of the best soft wrought iron, and is wound with a single magnetizing coil. The core is united at each end with one of the pole pieces which are of a high grade of cast-iron, and are extended to form feet upon which the motor stands. The switch for turning on and off the current is placed on the top of the motor. The 1/6 h. p. machines are wound for 110 to 500 volts, and carry a 12″ to 15″ fan. The 1-12 h. p. machines are wound for 110 volts with 11″ fans, and all sizes can be wound for any voltage desired, if so ordered.



THE CHICAGO FAN MOTOR.

These motors were designed by Mr. B. D. Sothard, and are manufactured by the Chicago Electric Motor Co., of which he is president and manager. This company also builds both motors and generators of all sizes for any class of work. The fan motors are very neat, durable, and efficient, and the workmanship is first-class in every detail.

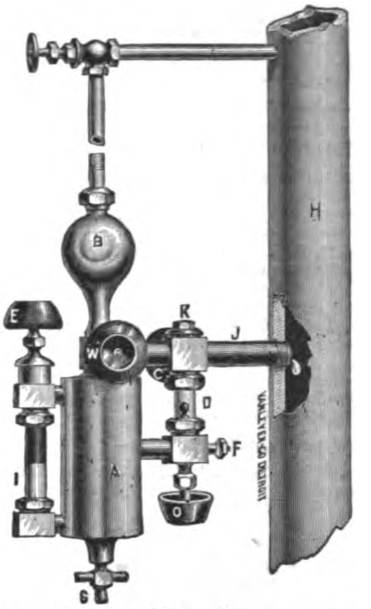
THE BALL ENGINE CO.

Owing to the great increase in the demand for automatic cut-off engines, the Ball Engine Co., of Erie, Pa., are now erecting a large addition to their works, which will nearly double the present capacity. In this extension they will set up their large engines, the building being built and equipped with special reference to heavy work, and giving unexcelled facilities for the building of high speed engines.

The company are now manufacturing their single cylinder, cross compound, tandem compound, and triple expansion engines, from 75 to 700 h. p., and also special vertical engines arranged to be directly connected to the dynamo, and suitable for use in electric lighting on ships, etc.; and it is stated that, in view of several important improvements recently designed, the engines hereafter turned out will excel anything ever built by the company in mechanical construction, economy of steam and general excellence.

THE "CYCLONE" SIGHT FEED CYLINDER LUBRICATOR.

THIS lubricator, shown in the accompanying illustration, has lately been produced by the Michigan Lubricator Co., of Detroit, Mich. As will be seen, the arms holding the glass are so arranged that the plug K may be removed at the top, and the drain valve F opened at the bottom, thus attaining a passage directly through the sight feed glass and permitting it to be renewed, cleaned, or drained, while the engine is running.



THE "CYCLONE" SIGHT FEED CYLINDER LUBRICATOR.

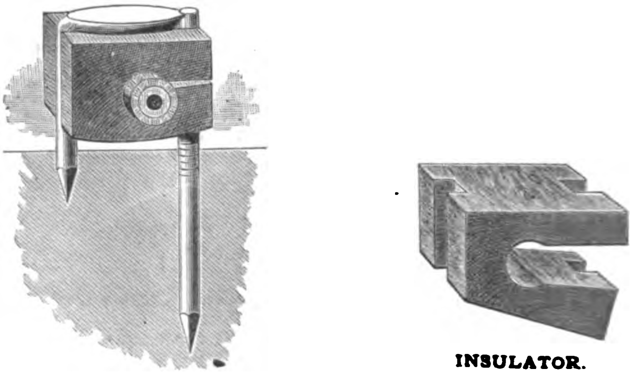
By removing the plug K, the sight feed glass may be wiped out, and at the same time filled with water to prevent waiting for water of condensation, or, if preferred, dry steam can be rushed through the glass, by closing the valve O, and opening valve C, and drain valve F, thus cleaning the glass without removing plug K.

This lubricator is finished in a variety of styles. The valve stems, packing nuts, and all parts are constructed in a heavy, substantial manner.

The cup fills rapidly, having a ¾ inch filling glass, which is vented at the rim of the filler, thus obviating much trouble and delay.

RUSH ELECTRIC WIRE NAILS AND INSULATORS.

The accompanying illustrations, Figs. 1 and 2, show an improved electric wire nail and insulator made by the Rush & Gildmeyer Manufacturing Co. of 1004 Walnut street, Philadelphia, Pa. As will be seen, the insulator will hold and firmly clamp the wire without injury to the insulation, no matter how hard the nail may be driven in, and, as the grain runs across the nail, it cannot split away. This insulator is easy to put on, quick to drive, and is especially useful in corners and concealed work. It has been approved by the New York and Boston Boards of Fire Underwriters.



INSULATOR.

Showing Insulator and Nail in position, with insulated Wire secured therein.

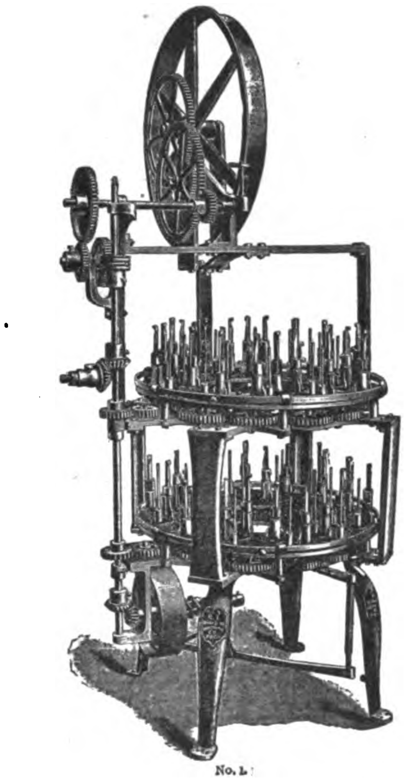
Free from all contact and firmly held.

Showing thickness of lower side, which closes up the opening as nail is driven in, and secures the wire firmly in the centre.

FIGS. 1 AND 2.—RUSH ELECTRIC WIRE NAILS AND INSULATORS.

A NEW BRAIDING MACHINE FOR COVERING ELECTRIC WIRES.

THE rapid development in electrical science, and the necessity for cables and wires covered with a suitable insulation, has opened the field for vast improvements in braiding machinery. Among the first to enter the field of manufacturing braiding machines for covering electric wires, was the Rhode Island Braiding Machine Co., of Providence, R. I., who have devised a number of useful machines for electrical purposes. We illustrate in the accompanying engraving their most recent production, which is well calculated to fill the wants of all manufacturers of insulated wire. The engraving represents one of their double braiders, with two sets of bobbins, 24 bobbins being in each set, and which is provided with a wheel take-up. This machine will cover the heaviest sizes of wires with two layers of insulation of 24 strands each.



RHODE ISLAND NEW BRAIDING MACHINE.

THE HOGGSON NEW SINGLE MAGNET BELL.

IN the manufacture of electric bells. although it may at first sight appear as though finality in simpleness of construction and reliability of operation had been reached, this is not the case and new improvements are continually being made. The new Hoggson bell, illustrated in the accompanying engravings, is seen to present some novel and advantageous features. Figs. 1 and 2 show the bell as finished either in square or round case.

HOGGSON SINGLE MAGNET BELL.

The armatures and magnet cores are coated with Banca tin to prevent corrosion. The armature springs are of German silver with platinum points, and the frames are japanned and so formed as to offer no inducements to insects.

These bells are adjusted to ring through a circuit of 200 feet of No. 18 B. & S. wire with two cells of battery, and are thoroughly well made. They are manufactured by the Stevenson-Hoggson Electric Co., of St. Louis, Mo.

THE PAISTE SWITCH SOCKET.

Many electricians have desired a socket that would carry and break 5 amperes, but heretofore this desire has never been catered to by electrical manufacturers. Mr. Paiste set to work and placed his well-known 5 ampere switch in a socket to make and break the circuit. His first attempt was not as satisfactory as he desired, the socket being made too large and unhandy to wire up. In the new style, which is just now being introduced, the socket shell is greatly reduced in size, making it the smallest socket on the market. Great care and attention was given to the manner of connecting the wires. By an ingenious device the wireman can use his discretion between a binding post and a binding screw. When in the act of wiring, both shells can be removed from the socket, leaving a clear, unobstructed place to work. By means of a yoke and collar the socket can be securely fixed to a chandelier, and under no circumstances can the shell short circuit the wires. All insulating parts are made of Syracuse china, insuring a perfect insulation. Central station men should appreciate this socket, as, by its use, one can, during the Christmas festivities, substitute large candle power lamps for the normal ones, without fear of destroying the working parts of the socket. Although not a cheap socket to make, through the agency of special machinery, it is offered in competition with those now on the market.

A PITHY TESTIMONIAL.

The Jerome Kidder Manufacturing Co. are in receipt of the following :—

NATIONAL SURGICAL INSTITUTE,
96, 98 AND 100 SOUTH PRYOR STREET, ATLANTA, GA., April 16, 1891.

JEROME KIDDER MANUFACTURING CO.,
820 BROADWAY, NEW YORK.

Gentlemen:—Please send us by Adams Express a No. 5 tip cell battery. We have been using one of these bought by our Dr. Kenouff, in 1887, and it gives more satisfaction than any other we have ever used, and we have tried several.

We are yours, very truly,
NATIONAL SURGICAL INSTITUTE, ATLANTA, GA.
Per R. H. BOLAND, M. D.

DETROIT TRADE NOTES.

MR. F. H. BLADES, of the Detroit Motor Company, reports the company as snowed under with orders for their well-known motors, and has a desk full of letters and dispatches calling for all sizes.

THE DETROIT ELECTRICAL WORKS during the past week have booked the following orders :—15 motors equipments for Lawrence, Mass.; 5 for Bristol, Tenn.; and 5 for Athens, Ga. They have just brough out a ⅙ h.p. fan motor wound for 500 volts, and operating in their offices from the street railway circuit to perfection. The little machine is quite a novelty in its line being, we believe, the first machine of such small size wound for so high a tension.

THE COMMERCIAL ELECTRIC CO. have issued a new catalogue of generous proportions and handsome typography. It contains cuts and description of almost every supply article imaginable. The book comprises some 300 pages, the first part being devoted to incandescent electric light supplies. Then follow arc lighting appliances, construction apparatus, miscellaneous tools of all kinds, wires and cables, and electric street railway supplies of every nature. A complete system of code words for facility in ordering goods by wire is a noticeable and most useful feature. A copy should be in the hands of every consumer of electric supplies.

THE COMMERCIAL ELECTRIC CO. are very busy in their construction department, they are building a 200 arc and 1,000 incandescent plant for the Western Electric Co., of Chicago, in Oil City, Pa. They are also going to build a plant for the village of East Tawas, Mich., and are now equipping the Hudson Building, Detroit, with a plant of 200 arc lights and 200 incandescents. In addition to the above they have several large and important contracts on hand.

THE FIELD ENGINEERING CO., Central Building, Liberty street, N. Y., have issued, in pocket folder form, some very interesting and useful data relative to electric railway work. Some of the figures should be in the memory of all who do construction work or are buying plants.

ST. LOUIS TRADE NOTES.

The American Electric Lamp Co. is the new name of the former American Electrical Mfg. Co., whose factory and office are located at 2011 to 2017 Pine street. The reason of their change of name is that they will now make a specialty of incandescent lamp manufacture and put a new perfected lamp on the market.

The Shultz Belting Co. are meeting with excellent success with their new link belt, which is giving first-class satisfaction on street railway work, as evinced by the strong testimonials for it that they are receiving. Their pulley covering is also having a large run, working with the most desirable results.

The Mid-Continent Mfg. Co., through their energetic manager, Mr. S. W. Baird, are pushing their well-known Brazelle governers for slide valve engines, and meeting with first-class success. These governors when placed upon an ordinary engine, govern the speed under the widest variations of load, and have only to be seen in operation, to be appreciated. An ordinary engine furnished with one of these governors, becomes self-regulating in speed for the most severe electric light and street railway service.

Mr. William H. McKinlock, of the Central Electric Co., of Chicago, Mr. Henry D. Stanley, of the Bridgeport Brass Co., of Bridgeport, Conn., and Mr. W. C. Bryant, manager of the Bryant Electric Co., also of Bridgeport, were visitors to St. Louis last week.

The Triumph Compound Engine Co., of Cincinnati, are introducing the Eickershoff patent valveless compound engine. The novel feature of this engine is the entire absence of valves in the ordinary sense of the word. The pistons themselves act as valves. The engine is of the upright type and has three compound single acting cylinders each cylinder having a high pressure and low pressure piston. The cranks are set 120 degrees apart, there is, therefore, no dead centre, the engine is perfectly balanced and will start from any position. Close speed regulation under wide variation of load is effected by a simple form of governor. The company have been quite successful in introducing their engines throughout the States and foreign countries. Many testimonial letters from electric light companies, and others have been received by the company. An extensive order has lately been received from Pittsburgh. Mr. Geo. W. Candle, No. 423 Washington Avenue represents the interest of the company in St. Louis. A number of contracts have been effected by him in this vicinity lately.

The Unicycle Elevated Railway Co.—It will be remembered that this company exhibited a small unicycle car at the St. Louis Exposition last fall, which created a widespread interest. The track on which this car was operated was perfectly straight and without grade and did not show the invention to its best advantage. During the past winter the company have constructed a full size car and elevated track with curves and grades so as to show the operation of the system under more crucial conditions. At the headquarters of the company, the old real estate exchange on Seventh street between Chestnut and Market, they have erected an elevated double track some 300 feet in length having compound curves of 10 feet radius, and grades of 5 per cent. The car and roadway are constructed on substantially the same plan as was described in **The Electrical Engineer** of October 8, 1890. The car is 16 feet in length and 6 feet wide, mounted on two unicycle trucks. Each truck is provided with two Sprague motors of 3 h. p. each, located on each side of the truck below the floor of the car. The motors are attached rigidly to the truck frame and are geared by single reduction gears 7 to 1 to the main driving wheels, which are 36 inches in diameter. The fields of the 4 motors are constantly excited. Current is admitted to the armatures through a regulating rheostat. The current at 220 volts is supplied by the St. Louis Electric Power Co., double trolley wires are used. The total weight of the car is about 7,000 pounds and it has a seating capacity for 20 persons. The work is now completed and the car in successful operation. The car passes around the short curves with perfect ease and safety. The exhibit is attracting the attention of all classes, capitalists and railroad people especially.

THE CENTRAL ELECTRIC CO, CHICAGO.

The Central Electric Company have their stores in Franklin street full of paper hangers and decorators, cleaning house for the summer.

The Okonite Base Ball Club are getting into good shape for the summer campaign and during the Saturday afternoons in June they can be found sprinting around one of the diamonds in Jackson Park and at other times are prepared to receive challenges at the office of the Central Electric Company, where they may be addressed.

In connection with the large arc lamp installation to be placed in the new Fair building of this city, the Central Electric Company has secured the contract for furnishing the wire, and of course, will supply the celebrated Okonite. This will be probably the largest insolated arc light plant in the country.

WASHINGTON NOTES.

Newport News, Va., has accepted a proposal from the Edison Co. for a central station.

The U. S. Electric Light Co. is now using Thomson-Houston alternating system in connection with the Edison. Georgetown is supplied entirely with the alternating system.

Capt. E. S. Randall has just put in a 30 light arc plant of the Edison system at River View, his summer resort on the Potomac.

The Regents of Mt. Vernon have made arrangements to use electric light on portions of the grounds at Washington's Tomb.

Rockville, Md., will erect a Thomson-Houston alternating plant during the summer.

The New National Theatre has contracted for a complete system of incandescent lighting, both on the stage and in the auditorium. The current will be supplied by the local lighting company,

WESTERN TRADE NOTES.

The Kerites, which is the auspicious name of the base-ball club comprising the employees of the Western Electric Co., are preparing for a busy season, in which they will probably measure bats with the Okonites again, whom they defeated in their contest early last summer. They expect to have an exceptionally strong team this year, and propose to be the champion team to meet the East in 1893.

The Sunbeam Incandescent Lamp Co. are just installing a new dynamo in their lamp factory and also another of the well-known Packard vacuum pumps, which are in use by almost all the lamp manufacturers in this country and in Europe. Their business has increased so rapidly that they have had to add this new machinery to keep pace with their growing orders.

J. A. Rhomberg, president of the Dubuque Electric St. Ry., of Dubuque, Iowa, was a visitor to Chicago last week. His storage battery cars there are operating very successfully.

Geo. Cutter continues to supply high insulation for odd places by sending out generous batches of rubber tape and of Simplex paint. He finds a good field for his "Rubber Elastic Tape," which is as pure as it is black, and which, like a good veteran, holds its ground without flinching.

Mr. H. H. Patter, of Monmouth, Ill., is in the city, and reports that his Lamp Hour Recorder is giving good satisfaction in the numerous places where it is used.

The Northwestern Electrical Specialty Co., Chamber of Commerce building, Chicago, through their energetic manager, Mr. Kirkham, report extensive sales on the well-known Economic incandescent lamp and that their orders are increasing all the time in a very satisfactory manner.

Mr. Jenkins, manager of the Omaha office of the Pond Engineering Co., is in town and will probably spend some time here, assisting Mr. Albert Blanchard, manager of the Chicago office, on the numerous contracts that he has in hand.

The Great Western Electric Supply Co. are doing a large business, and orders are coming in in good shape. The demand for the new Sun arc lamp for incandescent circuits is large, and inquiries are coming from all over. They are doing a brisk business, also, in general supplies of all kinds.

The Charles Munson Belting Co. are filling some large orders for their famous belting, which continues to give the highest satisfaction to users, for all kinds of heavy and severe work, and their belts for electric railway plants are meeting with specially favorable commendation.

The Illinois Electric Material Co. have recently been appointed general Western agents for the Russell arc lamps, which employ a circular carbon and will burn from 24 to 36 hours without renewal of carbons. They have already booked several orders for these lamps.

Bowers Bros., 121 Lake St., Chicago, are supplying most of the large electrical manufacturers with mica, of which they carry a large stock of fine grades, both domestic and imported.

The Hay-Horn Mfg. Co. has succeeded to the business of the Walter Hay Mfg. Co., and with larger capital and increased facilities, will extend its operations. Its headquarters are at 63 South Canal street, where it will carry on its operations as manufacturers' agent, contractors, etc.

The Thomson-Houston Electric Co. report the following recent installations made by its Western Isolated Lighting Department: Thos. Kane & Co., 137 Wabash ave., Chicago, 50 light incandescent plant to run in connection with Regan vapor engine; Wm. Ruehl Brewing Co., 224 West 12th street, Chicago, 200 light incandescent plant; Hager & Johnasen Mfg. Co., Marquette, Mich., 250 light incandescent plant; Ranken & Fritsch Foundry & Machine Co, St. Louis, Mo., 18 arc plant; Morrison, Plummer & Co., 200 Randolph street, Chicago, 250 light incandescent plant.

THE VALUE OF RAW HIDE PINIONS.

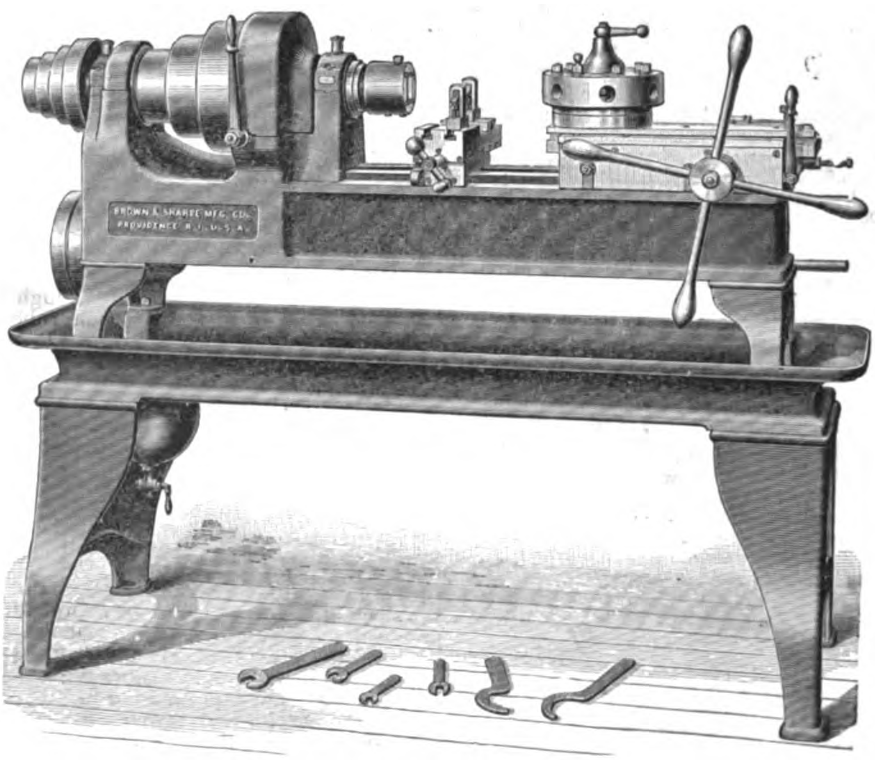
The New Process Raw Hide Co., of Syracuse, N. Y., are in receipt of the following from the Pleasant Valley Road, of Pittsburgh :—

I write to let you know of our continued success with your raw hide pinions. Have had them put to most severe tests on 12½ per cent. grades and find that they stand the work admirably. They will outwear steel and iron pinions, and are superior to bronze in many respects. Can especially commend your new "flange" pinion to roads having long or steep grades. We have tried *every* make of pinion known, metal and otherwise, and can say without any qualification that New Process Raw Hide has no superior.

Sincerely,
(Signed) WM. McC. RAMSEY.

THE BROWN AND SHARPE SCREW MACHINE.

The accompanying illustration represents the No. 6 screw machine, made by the Brown and Sharpe Mfg. Co., of Providence, R. I. This machine is suitable for making studs, screws, and a large variety of small parts of machines from the bar, also for finishing work held in a chuck when several tools are required or a number of operations are to be performed.



BROWN & SHARPE MFG. CO.
PROVIDENCE R.I. U.S.A.

BROWN & SHARPE NO. 6 SCREW MACHINE.

The head is back geared and the change from belt speed to back gears is effected, without stopping the spindle, by a friction clutch which is practically positive in its action and will hold the full belt power of the machine. The "back gears" are underneath the spindle cone and are entirely enclosed, as are also the gears on the cone. The cone has three steps, 6", 8¼", and 11" in diameter, and the back gears are 4.63 to 1.

The spindle is steel. Its front bearing is hardened, and both bearings are ground. It has a hole 1 7/16" diameter, and the front end is fitted for a chuck. The end thrust is taken by the rear box, and received directly on a hardened steel nut and washers. The spindle boxes are 2¼" and 2 13/16" diameter, 3 13/16" and 2 13/16" long. They are steel, hardened and ground. Number of revolutions of the spindle to 1" of movement of the turret head for each step of the feed cone, 50 and 96, 39 and 76, 29 and 52, and 21 and 36.

The turret is fed automatically, or by hand, and has eight speeds, as each of the four speeds given by the feed cones may be varied by shifting a lever, so that, without changing the belt, the tools may be fed fast or slow for each step of the cone. The turrett is 9⅛" diameter and has 7 holes 1¼" diameter. The movement of the turret head slide is 9⅝", and the extreme distance between the face plate and the turret is 32". The length that can be drilled, or milled, without moving the turret head slide bed, is 6".

The swing over the tool post slide is 6¼". Swing over bed, 18⅛", and length of bed, 56".

The counter-shaft has friction pulleys 14" in diameter, 3½" face, and should run about 175 revolutions per minute.

The floor space occupied by this machine is 30" × 78", and its entire weight is 1,800 pounds.

BALTIMORE ELECTRIC REFINING CO.

The new buildings for the Baltimore Electric Refining Co., at Baltimore, Md., will be made of iron designed and built by the Berlin Iron Bridge Co., of East Berlin, Conn. The rolling mill will be 56 feet in width by 180 feet in length. The refinery building will be 180 feet in width by 80 feet long, and the boiler house will be 49 feet in width by 50 feet long. The buildings will be entirely of iron, no wood work being used about the construction in any way.

PAGE BELTING CO.

The Page Belting Co. report recent orders filled as follows :— A complete outfit for the Beaumont Furniture & Art Wood Manufacturing Co., Beaumout, Texas, including a belt 20 inches wide, also a complete outfit of belting for the Mohawk Knitting Co.'s new mill at Mohawk, N. Y., and a complete outfit for the Pennsylvania Steel Co. at Sparrows Point, Md. Among the special belts of their make for running dynamos, shipments have been made during the last month to J. A. Grant & Co., Portland, Me.; National Sewer Co., Newport, Ohio; Forbes, Liddell & Co., Montgomery, Ala., and the Electric Forging Co., of Boston. Among the large main belts furnished have been belts to the Des Moines Manufacturing & Supply Co., Des Moines, Iowa; to the McNeil Pipe & Foundry Co., Burlington, N. J., and to Gaines & Glover, Richmond, Va.

MR. CHARLES A. BROWN, manager for the Western Electric Company, Chicago, having graduated in law a year ago, is about to sever his connection with manufacturing and commercial business. He has formed a partnership with Mr. George P. Barton, of Chicago, to conduct a general law business, making a specialty of patent law and allied branches of practice. The new partnership will go into effect July 1, next.

THE EMERSON ELECTRIC MANUFACTURING CO., of St. Louis, are now working night and day turning out their numerous lighting and railway specialties and their new alternating fan motors which have only to be seen to be appreciated.

MR. F. A. ROSS has resigned as manager of the Livingston Electric Light Co., of Livingston, Mont.

"THE ELECTRICAL ENGINEER" IN PHILADELPHIA.

Owing to the rapid growth of electrical industries in Philadelphia, and of the business relations of THE ELECTRICAL ENGINEER with that city, this paper has established an office there at 714 Girard Building, Broad and Chestnut streets. This office will be in the charge of Mr. Wilbur F. Hanks, who is already very favorably known in that section in connection with electrical journalism, and Mr. Hanks has now entered upon his new duties. In making this announcement, THE ENGINEER asks, with confidence, that its many friends and readers upon whom it will be Mr. Hanks' pleasant task to wait, from time to time, will favor him with full and early news, so that the interests of his territory may be thoroughly represented in its pages.

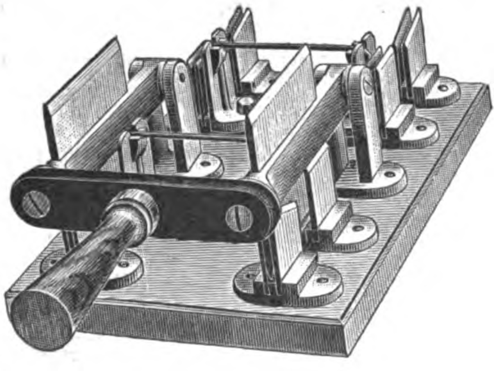
PHILADELPHIA NOTES.

H. T. PAISTE, the enterprising electrical specialty manufacturer, of Philadelphia, recognizing the want of a store room and office in Chicago, has opened out at 341 The Rookery, that city, where his Western friends and patrons can be supplied without having to order from the factory in the East. The move seems a popular one among the supply men of the West, as it will save them the necessity of ordering in large quantities to save freight and express rates. Mr. Paiste still continues his Eastern office and factory at 1201 Market street, Philadelphia. The Western office will be managed by Messrs. Kohler Bros. and Grier, three enterprising young men, who will do all in their power to cater to the wants of the Western electrical trade in Mr. Paiste's line of specialties, which consists of porcelain base switches, china switches (which are decorated in all tints to match wall paper), sockets, cut-outs and gas attachments.

MR. S. ASHTON HAND, of Philadelphia, a widely known mechanical engineer, member American Society Mechanical Engineers, and lately general superintendent for Morris, Tasker & Co., has joined the forces of the Equitable Engineering & Construction Co. Mr. Hand will take entire charge of the mechanical engineering department of the Equitable Co., whose offices are in the Drexel Building, Philadelphia.

THE "BAGNALL" FUSE SWITCH.

THE demands of the electric railway service call for some automatic device which will afford absolute protection against excessive current in the feeder wires, and which can be readjusted without loss of time. For this purpose the circuit breaker of various forms has been employed, and while it has many advantages over the ordinary form of fuse block, nevertheless, on account of the mechanical nature of the device, it is liable to fail in its operation by sticking or getting out of adjustment.



BAGNALL FUSE SWITCH.

The Bagnall fuse switch, made by the Emerson Electric Mfg. Co., of 518 Elm St., St. Louis, Mo., embodies the certainty, simplicity and cheapness of the fuse with the convenience of the circuit breakers.

It is a combination of a fuse block and a switch, having a double or relay fuse which can be thrown in instantly when the first fuse melts. The fuse, which is the ordinary fuse wire bent into U shape with the fingers, is inserted in the fuse block without the use of any screw-driver or other tools, and the contact is automatically made and the fuse firmly clamped when the switch is thrown in. It is the work of but an instant to put in the fuse, and all danger of premature fusing is prevented, as the fuse terminals are completely isolated and disconnected by the opening of the switch.

Two styles of these switches, a single and a double, are made. The latter, shown in the accompanying illustration, provides a relay fuse, always ready to be thrown in. They are substantially made, on polished slate bases, and are valuable adjuncts to the operation of central power and lighting stations.

Financial Market.

THE OUTLOOK FOR ELECTRICAL SECURITIES.

Nothing frightens purchasers of stocks and investment securities more than large exportations of gold. Speculation has been from time to time almost stopped by the heavy demand made on this country for gold on foreign account. At this time, however, while the demand from abroad has been especially great, people are beginning to realize that this country is the only one at present in position to supply gold, and the market is thereby strengthened. Our ability to supply the precious metal has had the effect of making England a heavy buyer in our markets. That country has rarely shown the confidence in American securities that they deserved, and America in turn has given too much attention to English demand, when it came, for our stocks and bonds. The market here has many a time been thrown entirely off when every indication was favorable to the purchase of stocks, by the large selling orders from London. The present condition of affairs would indicate that independence of such foreign influence is tending to the betterment of our own securities.

Apparently everything is ripe at the present time for an upward trend of the market. A temporary reaction may come, but it will not hinder a general rise in the market for any great length of time. The condition of the crops is good, and we are happily free from any immediate Congressional legislation.

One of the best evidences of the strength of electrical stocks is found in their activity during a depressed condition of the general market. Few stocks stood as well during the panic, and few indeed have been the railroad shares that showed so little depression during the last few weeks.

Generally speaking, the electrical stocks that are listed are dividend paying stocks, and it is hardly possible for them to fall like some of the so-called "fancies" on the New York Exchange. Generally they represent good investments, and at present prices may be considered cheap. These stocks are better understood and appreciated now than ever before.

Bonds on electric railways in large issues, in cities of 40,000 population and upwards, are finding a ready market, but bonds in small issues, representing small street railways, are very difficult to sell. Banks and trust companies, not having special facilities for examining these securities, are seldom attracted by them, unless the price is considerably below par for small issues. Another reason for the slowness with which these small bonds are marketed is demonstrated by a procedure similar to this: A couple of promoters succeed in getting a franchise to run an electric railway through a small town. It needs but a small expenditure of money to obtain the franchise, the company is formed and the stock of the corporation put into the pockets of the promoters, practically costing nothing, and the bonds are issued to pay for the building of the road. If the road can pay operating expenses and interest on the bonds, all is well; if not, the bondholders have only a secondhand road for security, and not being able to get out what they put in, will cry out with all their strength against electrical securities in general.

There are as good opportunities to make large profits in electrical bonds as can be had in any market. It is an easy matter to sort the good from the bad, and none but the best investments need be taken up. Electrical bonds can easily be found whose security is undoubted, and these bonds can be had at from 90 to 95, whereas railroad bonds, with no better security, sell for par.

The market for electrical stocks has been active during the week. Edison stock has strengthened and closed at 100 bid, 102 asked. Thomson-Houston has been steady, closing at 44 bid, 44¼ asked. Bell Telephone closed at 199 bid, 200 asked, and is likely to see a rising market in a very short time. At the present price Bell Telephone stock can well be considered cheap. Westinghouse fell slightly from last week, but will likely recover during the coming week. The stock closed 14 bid, 14⅛ asked.

FRANCK Z. MAGUIRE.

THE CONDUIT WIRING CO.

The above company have started in business at 12 West 29th street as electrical contractors, and with special authorization from the Interior Conduit & Insulation Co. to put in the conduit system. They will make the proper installation of interior conduits a leading feature of their business. They are also prepared to make contracts for complete electric light installations or for electrical apparatus of various kinds. Mr. C. J. Klein is the president and general manager of the new concern, and Mr. S. Davis is the secretary and treasurer. The latter has long been engaged in engineering work, and the former needs no introduction to the electrical community. They invite correspondence and calls at their office and show rooms.

THE
Electrical Engineer.

VOL. XI. JUNE 3, 1891. No. 161.

THE WRITING TELEGRAPH.

MANY of our readers will remember the introduction some time ago of a system of transmission called the "Writing Telegraph," which attracted considerable attention on account of its novelty, and the simplicity of its operation. The system, which was introduced by the Writing Telegraph Company, of this city, consisted, in brief, of a transmitter which served to vary the current on two lines connected to the receiver. The latter consisted of a pair of electro-magnets placed at right angles to each other and acted upon an armature which followed exactly the movements of a stylus in the transmitter; this stylus served to vary the currents on the connecting lines by cutting in or out a set of resistances.

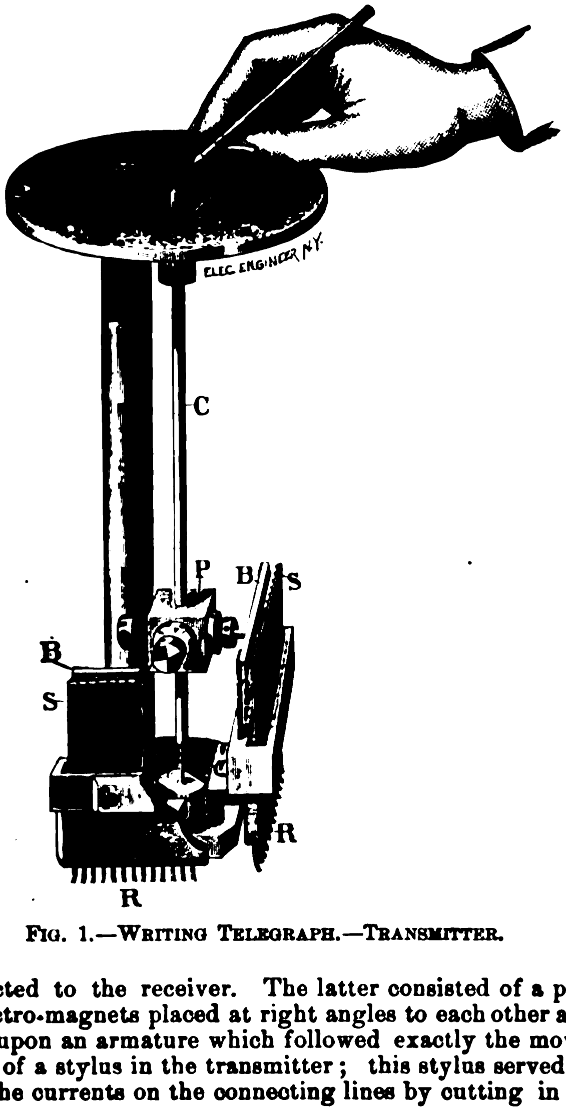


FIG. 1.—WRITING TELEGRAPH.—TRANSMITTER.

After many trials and experiments, the "writing telegraph" may now be said to be in a perfected condition, as evidenced by the work it is able to do, and which we had occasion to witness recently.

The transmitter, which fully meets all the requirements for electric writing, is the invention of Mr. Harry Etheridge. This part of the apparatus, which is shown in perspective, in Fig. 1, consists of a top plate, which rests on top of the case. A rod depends from this plate and supports the base. Secured to this base, and arranged at right angles to each other, are two receptacles, in which two series of steel spring tongues, S S, are separately held in a vertical position by an insulating cement.

The spring tongues are placed in line with each other, edge to edge, with a sufficient space between them to avoid contact. They are also hardened and tempered so as to readily return to their normal position, after pressure on them is released. To the lower end of these tongues a series of resistances R are secured, while their upper ends are provided with platinum contacts.

Supported from each holder by two spring strips, which are insulated, is a brass contact bar B, having its side next to the steel tongues and arranged at an angle thereto. These two contact bars are each provided with a platinum wire placed opposite the platinum contacts of the spring tongues, and by reason of their spring supports can be brought in contact with the tongues, each tongue making contact independently of the rest.

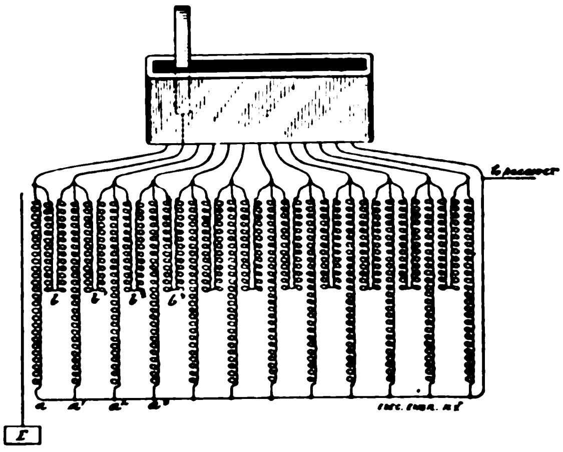

FIG. 2.—ARRANGEMENT OF RESISTANCES IN WRITING TELEGRAPH TRANSMITTER.

The stylus rod C is screwed into the base, and its spring at the lower end allows of a free movement of the upper end in any direction. A pressure block P, as shown, is secured to the stylus rod. Two adjustable pressure heads are screwed into this block and held tightly by locknuts in whatever position adjusted.

When the stylus is in its normal position, the pressure heads are so adjusted that contact is made with the projection on the contact bar, and the contact bar with the first spring tongue, whereby any lost motion is prevented.

When the stylus is operated, the contact bar is pressed against the tongues, making contact with a greater or less number, according to the extent of movement of the stylus, thus cutting in, or out, the resistances required to regulate the movement of the receiving pen. The resistances are arranged to avoid any break of circuit or oxidation at the contact points.

There are two series of resistances employed for each set of tongues and both connected to them in the manner shown in Fig. 2. One a, a^1, a^2, etc., is arranged in parallel arc, the other b, b^1, b^2, etc., in series, and both combined. The resistance of a^1, measured in ohms, is the same resistance as b. The resistance of a^2 is less than the resistance of a^1 but is the same resistance as b^1, and so on, the resistance continuing to decrease from a maximum resistance arranged farthest from the receiver to a minimum resistance; the last tongue to make contact with the contact bar controlling the lowest resistance.

The operation is as follows: When the tongues are out of contact with the contact bar, the current circulates in every branch; being of course, proportional to the resistance. When, through the movement of the stylus, the contact bar touches tongue No. 2, the resistance a^1 is placed in parallel arc with resistance a, while the resistance b, of resistance equal to a^1, is practically electrically cut out. The resistance b therefore prevents an open circuit in a^1 when contact 2 breaks contact with the contact bar, balancing the resistance a^1. In other words, the resistance b offers another and equivalent passage for the current the moment a^1 is separated from a, and so on throughout the remainder of the arrangement of resistances.

This transmitter has been used in commercial work with heavy battery for months and has never required touching. It has been tried in every style of work expected of the system and been found reliable.

Twelve contacts give all the variation required for any length of line. A parabolic curve, Fig. 3, describes the curve of resistances, and the same curve is used for all lines. The current used varies from a minimum of .0165 to a maximum of .03 of an ampere.

The receiver, which is shown in Fig. 4, has been changed, as shown in the cut, so that the only adjusting screws about the apparatus are one for each magnet, and these raise or lower the cores to or from the armature, when being adjusted to the line. The double armature, magnetically connected, and the float employed to remove the tremor of the armature rod, are retained. There is an armature (not shown) under the cores of the magnets which releases the paper-moving mechanism. Under the top plate of the transmitter are contacts which automatically cut out the transmitter when the stylus rod is released—and also a contact for calling up when placed in an exchange system.

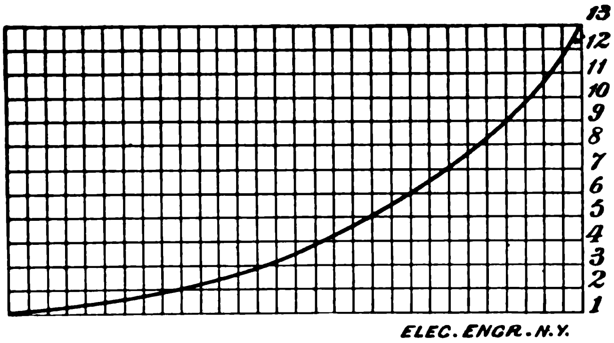

FIG. 3.—CURVE OF VARIATION OF RESISTANCES.

The greatest distance over which the instruments have thus far been operated was between New York and Pittsburgh on May 3, the distance being 468 miles; the wires were of copper, No. 12 (Stubbs) gauge, and the resistance was 2,550 ohms. The current used was from a test dynamo of 100 volts. This was all at the Pittsburgh end, and fed to both lines.

The insulation resistance should have been 12,000 ohms on each line, but, on account of the rain, this resistance on one line measured 6,700 ohms, and on the other 5,200 ohms. Notwithstanding the great loss of current thus incurred, there was the usual ease and speed in writing. The test showed to good advantage this manner of writing, as the stylus rod is always moved sufficiently for the receiving pens to form a perfect letter. Any variation of the battery or resistance on the line is overcome automatically by the operator unknowingly pressing his stylus rod laterally or downward, as the case may be, an infinitesimal fraction of an inch, to cut out the necessary resistance to form a perfect letter; the reproduction will evidently be a corresponding duplicate at the other end of the line.

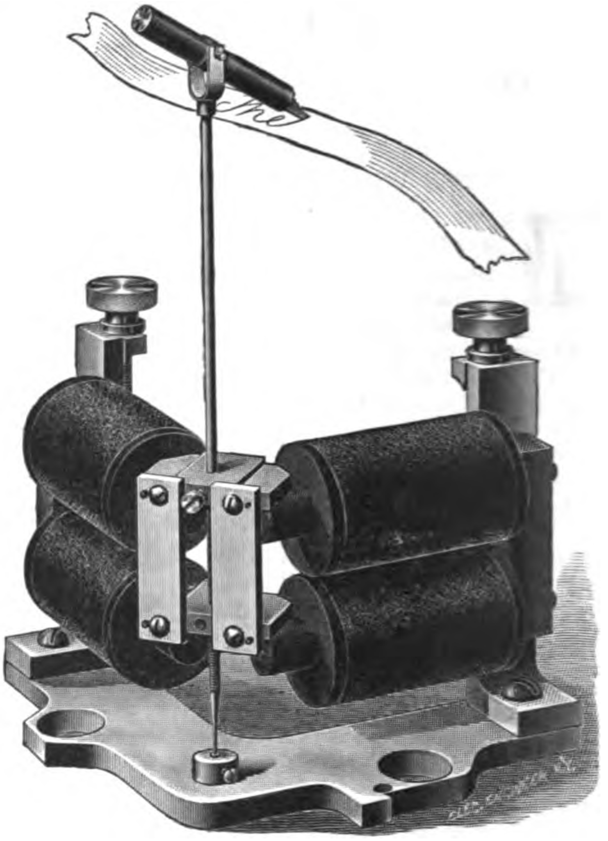

FIG. 4.—WRITING TELEGRAPH.—RECEIVER.

The test of operating between New York and Pittsburgh has convinced the company that they can write with the greatest ease over much longer lines and without relaying.

COST OF POWER TRANSMISSION.

THE following comparisons of the cost of transmitting power by various methods appeared in the *Revue Universelle des Mines*: 1. Comparative cost on 10 e. h. p., transmitted 1,093 yards: by cables, 1.77; by electricity, 2.21; by hydraulics, 2.90; by compressed air, 2.98. 2. Comparative cost on 50 horse-power, transmitted 1,093 yards: by cables, 1.35; by hydraulics, 1.87; by electricity, 2.07; by compressed air, 2.29. 3. Comparative cost on 10 effective horse-power, transmitted 5,465 yards: by electricity, 2.64; by compressed air, 4.66; by cables, 4.69; by hydraulics, 5.29. 4. Comparative cost on 50 effective horse-power, transmitted 5,465 yards: by electricity, 2.37; by cables, 2.65; by compressed air, 2.99; by hydraulics, 3.02. Steam was the prime motor used in each of the above instances, and it appears that for long distances electricity takes the lead in economy over all other systems.

FRANKFORT EXHIBITION.

THE Grand Duke of Weimar has lent the Exhibition authorities the electric machine with which Goethe made his experiments, and which is included in the relics in the Goethe Museum at Weimar. The Congress of German Municipal Authorities, to be convened by the chief magistrate of Frankfort during the Exhibition, is to be held on August 27th, 28th, and 29th. The two electrical boats which will be on the Main during the Exhibition are to be accompanied by a boat propelled by a petroleum engine. The engine will also drive a small dynamo which will generate current for the lights.

ELECTRICAL ENGINEERS.

ALBERT SCHMID.

Mr. Albert Schmid, the subject of our portrait this week, is a native of a country famous for its mechanical wonders and engineers, having been born in Zurich, Switzerland, in the year 1858.

Mr. Schmid received an elementary education in the well-known schools of that town, and at the age of 14 entered the shops of one of the largest Swiss engineering firms, where he remained five years, going through all the departments, including the drawing office, as well as erecting machinery for this firm throughout Europe, thus receiving a thorough practical engineering training. Leaving this establishment, at the age of 19, a skilled mechanic and competent draughtsman, Mr. Schmid entered the celebrated Swiss Engineering University of his native town, from which he graduated two years later with a splendid equipment of theoretical and practical knowledge, which he has since used to such good advantage. He then associated himself with Carrels Brothers, the well-known Belgium locomotive builders of Ghent, where he was employed for some time designing locomotives, Sultzer engines, and in general engineering work. Desiring to get a broader experience, he next engaged with the renowned engineering firm of Easton & Anderson, of London, England, in the same capacity. By his work here he established a reputation which attracted the attention of a well-known French electrician, who induced Mr. Schmid to become connected with him in some electrical experiments for the Westinghouse interests in Paris. After completing this work he was brought to this country in 1884 by Mr. George Westinghouse, Jr.

Albert Schmid

The Westinghouse Electric Co. was organized about this time and Mr. Schmid was made superintendent, in which capacity he still serves that company. In this position Mr. Schmid's varied experience and thorough training has had an opportunity to demonstrate itself, the mechanical design of the apparatus manufactured by the Westinghouse Company bearing excellent testimony to his ability and knowledge of electrical matters.

Mr. Schmid's executive capacity is displayed by the perfect system with which the Westinghouse Company's shops at Pittsburgh are laid out and operated.

He has kept well up with the vast strides made in electrical science in the past decade, and, being endowed with considerable inventive talent, has contributed largely to the electrical perfection which the Westinghouse apparatus has attained.

Mr. Schmid has taken out a number of valuable patents, many of which, on electrical subjects, are controlled by the Westinghouse Electric & Manufacturing Company, besides which he holds a number of various mechanical devices. His new gas engine was illustrated in these pages **a few weeks ago.**

Mr. Schmid is a member of the American Society of Mechanical Engineers, as well as of the American Institute of Electrical Engineers.

LEAD COVERING FOR ELECTRICAL CONDUCTORS.

BY

L. D. [illegible].

To anyone unaccustomed to lead working it may seem the easiest thing in the world for a metal like lead, which is so easily melted, moulded or hammered, to be forced around a core bar and through a die for the purpose of making lead pipe.

Given the conditions of unlimited power and space, it might perhaps be an easy matter, but brute force is not science, and on scientific principles alone, is economy possible either in construction or production. Economy is the ruling factor in all commercial processes, and power and space are two of the most important elements on the reduction of which, to a minimum, success will greatly depend. The efforts of inventors have, during the last few years, been energized in this direction, with the result that lead covering machinery has been greatly reduced in size and weight, and the power required to drive it diminished, but it has, unfortunately, also become more intricate and sensitive.

Lead, though apparently so easy a metal to handle, is really one of the most sensitive to slight changes of mechanical working conditions when under high temperatures. That it melts and becomes very fluid at about 600° Far. is well known; but just at what temperature it is neither fluid nor solid, but only fit to make pipe, is a matter of considerable uncertainty. At its plastic point, or when just hot enough to make pipe easily, a very slight change in temperature will create a very considerable change in its condition, so much so, that the pressure required to force it through the die will vary from fifty to one hundred per cent.

The right temperature can only be got at by "rule of thumb," or by the negative process of finding out what is the wrong temperature. An old pressman whom I questioned on this point replied : "I don't know when I've got the right heat, sir, but I knows when it't too hot and when it't too cold, so I steers between the two." And this, I think, embraces the philosophy of the whole science of pipe making.

It is true that all doubt and possible failure on the question may be avoided by making lead pipe from cold lead, but this is a return to first principles, and is never done save when, as in the case of covering electrical conductors insulated with gutta percha, or some similar gum or compound, and which melts at less than 212°, the hot lead process is inadmissible. Of course to make pipe by the cold process necessitates great pressure and involves very heavy and powerful machinery.

By the hot lead process the pressure required is about one-tenth, and the weight of the machinery and power correspondingly diminished. Among other peculiar properties, lead possesses the greatest possible objection to being drawn over itself, hence, perhaps, the reason of the great power required to create its flow when plastic, so as to convert its solid mass into hollow and comparatively thin pipe. Anyone who has tried to take up the slack of a lead covered cable, even when cold, by drawing it over the other coils on a reel or drum, will have noticed this. It is almost impossible to do so, whereas with iron or brass it would have been easy enough.

To make lead pipe alone by the ordinary overhead press is a process requiring much experience and close attention, but when it is required to lead cover electrical conductors, the conditions are more exacting, and the difficulties increased. If a length of lead pipe is spoilt by accident or carelessness, which, however, but very rarely happens, it is simply returned to the melting pot, and the loss incurred is only that of labor and fuel, but in the case of covering such conductors as, say, a telephone cable, the result of an error is that the cable is either spoilt entirely, or at least has to be withdrawn from the press, stripped of its lead and the whole process commenced "de novo," a tedious, expensive, and dangerous piece of work.

There is a modification of the cold lead process by which conductors have been covered of late years to a considerable extent with more or less success. It consists in drawing the cable through short lengths of pipe which are afterwards jointed with an ordinary plumber's "wiped" joint, but it embodies so many disadvantages that it has fallen into very just disrepute. It is impossible to so cover more than very moderate lengths of cable; the joints are always weak places, require the best of skilled labor, and they take up valuable space. Besides this, as the pipes must be large enough to admit the cable to be drawn into them without excessive strain, which might damage it, the conductor cannot possibly be concentric with it, and thus a larger pipe than is really necessary is unavoidable.

When, however, the insulating material employed is one which has a high melting point, or, as in the case of fibrous insulation, no melting point at all, the hot process is the only one commercially practicable.

It does away with intermediate joints, may be made to cover cables of any length in one piece, and can also be designed to fit the cable so exactly that moisture is excluded without undue pressure on the insulation.

The machinery required is very simple. The cable is passed through a hollow core bar and a die which are seated in steel "blocks." These blocks are provided with an opening on the top, through which lead is forced by hydraulic pressure from a "lead cylinder" around the "core-bar" and through the "die," and thus becomes pipe, which on its way fits closely enough on the cable to drag it through the blocks, from which it emerges lead covered.

But whether the lead is put on by one or the other process there can be no doubt that it is surely working its way to the front rank as a cable covering. For submarine work, of course, it is out of the question, and its place is taken by lighter hemp and more flexible wire armoring, but for all other purposes it is recognized as the best, if not the only absolute, protection for electrical conductors, more especially for underground work.

In the early days of its adoption, specifications required that lead covered cables should be placed under water for at least two days and nights and then tested. The writer remembers one specification calling for immersion under water for a stated time, one end of the cable to be hermetically sealed and the other attached to an air pump. Air was then forced in so that escaping air bubbles or their absence decided the refusal or acceptance of the cable. But experience has proven all such tests to be unnecessary with the hot lead process, and like plumbers' and gas fitters' pipe, cables are now accepted with their lead covering as perfect, without the formality of other than the ordinary electrical tests. That this may be done with perfect security is evident from the very nature of the process.

The pipe must be either perfect or absolutely bad. Neither cracks, pinholes, nor other hidden faults are possible with a soft metal like lead, which, when heated to something less than melting point, is submitted to a pressure ranging from four to seven hundred tons. If there is a fault, it is flagrant and unavoidably perceptible. It may arise from the lead being too hot or the pressure too sudden, in which case a blow-out or "squirt" happens and the pipe is severed with a gaping, ragged edge.

Or, if the cable is hauled on too strongly and allowed to pass through the blocks faster than the pipe is formed, the latter will either be reduced in diameter, or, which is more probable, it will be torn apart; in either case it is impossible for such a fault to pass unnoticed.

The only other case which has ever happened in an experience of some thousands of miles of conductor, is cited as a curiosity rather than a liability. A small piece of the die broke off and became embedded in the pipe, from which it afterwards fell when the cable bent on the reel, and it had to be stripped and re-covered. The chance of such an accident ever recurring is too remote to be worth serious consideration.

When everything is in first-class condition the surface of the lead, as it issues from the press, should be perfectly smooth and polished, and its outline straight and cylindrical. If the cable is sinuous or "snakey" the pipe is either too large for the cable or the cable has been obstructed in its passage through the "blocks" and the pipe forced out faster than the cable has followed.

If the surface of the lead is dull and rough or tinted, it is proof that it has been made too hot, and cable so covered is more brittle and difficult to draw through a conduit than it should be if properly made. Too much heat is also indicated by the presence of minute fissures on the surface of the pipe at right angles to its length. These are, however, only on the surface, and I have known in a case of emergency, such pipe accepted and laid, and which, although exposed to the most unfavorable conditions for some years, is still giving perfectly satisfactory results. These are the only faults to which lead covering is liable. It must be admitted that they are few and within easy reach of avoidance by the use of care and watchfulness.

We may therefore conclude that under ordinary conditions, lead is practically a perfect, if not an everlasting, cable protector. It is no argument to say that lead will fail under conditions such as those of special and extraordinary chemical action, which would destroy any metal; but even there lead will hold its own, for the salts formed on the surface generally make a crust which prevents further action beneath it.

The writer has handled lead pipes which were laid down in Pompeii more than eighteen hundred years ago. Some six years ago they were in use for conveying water, to all intents as good and sound as when laid. It may be objected that no parallel can fairly be drawn between lead pipes which have lain under ashes and scoria for eighteen centuries, and those laid in our great modern cities, in conduits exposed to destroying gases and corroding effluvia. But it is a very fair comparison. Those pipes were laid underground long before Pompeii was buried, and judging from appearances, the inference is unavoidale that dirt and filth flourished there in much greater luxuriance than even in that queen of dirty metropolises, New York.

The use of lead is, after all, but a return to first principles. It was one of the first protectors of electrical conductors tried some fifty years ago, but abandoned on account of objections which, in this age of progress, vanished before improvements which render its application not only easy, but successful. Lead covering, as applied to-day, is as perfect as it is possible for anything to be, and experience only goes to confirm the idea that age in nowise impairs its protecting powers.

ON THE MEASUREMENT OF POWERFUL CURRENTS WITH A MIRROR-GALVANOMETER.[1]

BY A. OBERBECK.

By the principle adopted by the author, "the most powerful currents, without the addition of any shunt, give such small deflections that they can be measured with a mirror-galvanometer." A circuit of small radius surrounds a small magnet needle placed at or near the axis of the circle, and deflects the needle more strongly than a second circuit, the radius of which is greater. The two circuits being placed concentrically in the same vertical plane, they can be shifted to such a distance from the needle that their influences on it are equal, and if the directions of flow are opposite, the needle will remain in its normal position. By placing the circuits at a distance from the needle suitable to the strength of the current to be measured, the desired small deflection can be obtained.

CENTRAL STATION MANAGEMENT AND FINANCE.—V.

BY

Horatio A. Foster

Store Department.

The blanks for use of the Storekeeper are No. 11, order for stock, a tag for lamp, motor or transformer, in fact any article returned from outside the station for repairs or anything else; Blank No. 12, his weekly report for supplies used; No. 13, for operating, and No. 14 for construction material.

Blank No. 13.—Storekeeper's Report for Operating Material.

(Form 14.) [illegible]

CONSTRUCTION SHEET.

Storekeeper's Report for__________ending__________189 Entered Journal, page______

	Pole or overhead lines.	Price.	Amounts.			Inside wiring.	Price	Amounts.			Station and buildings.	Price.	Amounts.	

Blank No. 14.—Storekeeper's Report for Construction Material.

The above blanks are all very simple, and with the exception of No. 13, require no explanation. No. 13 is made by the week and each day is stated, as it is then easy at any time to divide the week into any parts, as, say, when the first of a month comes on Thursday, and all other reports are made from the 1st to the 31st.

The writer advocates the keeping of a regular supply account in the ledger, to which are charged all bills for supplies entering the station, and to which are credited all supplies taken out for the business, as per the weekly reports No. 13 and 14, which can then be journalized like any other bill. When this is done it is easy to give a complete and quite accurate statement of the financial condition of the business at any stated time, say monthly, and the balance of the supply account can be tested yearly by a complete inventory of stock on hand, when any difference can be charged off. The storekeeper should also be provided with a blank receipt for goods sold outside. No special form is mentioned here, as there are many good ones already made, which can be procured at any stationery store.

LEAD TUBES IN SALEM.

The telephone linemen in Salem, strung a lead tube along Front street and up Washington as far as the central office. In this tube were 65 telephone wires. These will take the place of the half a hundred now strung on poles along the same streets. The wires have rusted out very quickly the last few years from the effect of the salt air on them.—*Boston Transcript.*

STANDARD CELLS.

BY

H. S. Carhart

YOUR issue of May 20 contains an account of a new form of Daniell standard cell, by Mr. Carl Hering. It was not new to me, though just as original as with Mr. Hering, for I have one, made some months ago by two students at my suggestion. The only difference is that I use two hard rubber stop-cocks instead of wire pinch-cocks, as shown in Mr. Hering's illustration.

The effect of pressure upon E. M. F., mentioned by him, is not quite new, as may be ascertained by referring to Tommasi's "Pile Electrique," p. 364. The suggestion that the necessity of freshly electro-plating the copper electrode, every time it is used, might be avoided by amalgamating the copper, would be a very disappointing one to put into practice; for amalgamated zinc and amalgamated copper give a much smaller E. M. F. than the normal one of the Daniell cell. Moreover, it is quite as important that the zinc should be as free from oxide as the copper.

Considering these facts, and the extreme difficulty of preventing admixture of the two sulphates, whoever has had the use of a good Clark cell will never be willing to employ the Daniell except in case of necessity. The high temperature coefficient of the Clark cell can hardly be urged against it now, since its value has been reduced to half its former one. The editorial remarks in THE ELECTRICAL ENGINEER on existing standards of E. M. F. appear to throw some discredit on them. As an indication of their permanence and reliability I shall take the liberty of quoting some figures which I have obtained.

I have a Clark standard which I made four years ago after Lord Rayleigh's directions. It was one of the very first cells I ever made. Two months ago I made two more, again in accordance with Lord Rayleigh's directions. Of course the materials were from entirely different lots. In addition, I have a Rayleigh cell, four years old, put up in a wide-mouthed bottle. This has been used promiscuously by perhaps one hundred students in the laboratory. A comparison of the four cells on April 1 gave the following relative values of the E. M. F., the numbers given being the ohms required to effect a balance by the Rayleigh method of comparison:

Old Rayleigh Cell - -	at 20°.5C.	9,118
First new Rayleigh Cell - -	" "	9,118
Second new " " -	" "	9,116
Cell in bottle - - - -	" "	9,117

One week later at 12°.7C. the first three gave 9,179, 9,176, 9,176, respectively. The other was not compared.

I have ten cells, of my own special make, in a rack by themselves that never, I think, show an extreme difference among them of more than five parts in ten thousand. I consider Clark standard cells quite indispensable in an electrical laboratory.

SIMS-EDISON TORPEDO.

THE first exhibition in Europe of the Sims-Edison torpedo lately took place at Harve, on the coast of France, and with success. Representatives of the English, French, Spanish, Russian, Italian, Turkish, and Japanese governments, and the principal daily papers, watched a semi-public trial at the same place, as guests of the Société des Forges et Chantiers. Mr. Sims was in charge of the switchboard, and directed the operations of the torpedo, which made a long circuit and returned towards shore. The speed and complete submission to the will of the operator were clearly demonstrated.

DEMING'S AUTOMATIC SAFETY ELECTRIC SYSTEM FOR RAILWAYS.

BY

Edward P. Thompson

In safety systems now in use accidents still continue, not because the systems get out of order, but because some one is careless or forgetful, or because there is some "good reason" why the signal was neither heard, nor seen, nor set. Man cannot be depended upon as well as something which is automatic in its action. Thus, in case of a train going at the rate of 60 miles per hour, 20 seconds of inattention or absent-mindedness may cause a frightful accident.

Mr. Edward Deming, of this city, provides a system such that if two trains are approaching each other at any speed, and without an engineer or other person on board, both trains will stop when within a predetermined, or dangerous, distance of each other. The same system operates to stop a train approaching a stationary train from either direction, or an open bridge or switch, or grade crossing where two trains are about to collide at the crossing.

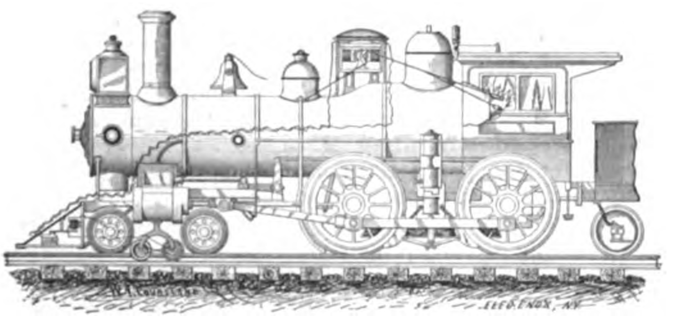

Fig. 1.

The system is operative, therefore, if a fog exists, or the engineer is thinking about other matters, or is color blind, or the curves are short and numerous. It is controlled by apparatus located upon the two trains; or upon one train on the one hand, and on the switch, bridge or crossing, on the other.

The system is illustrated in the accompanying engravings, Fig. 1 showing it as applied to a locomotive, Fig. 2 to a draw-bridge, and Fig. 3 to a crossing. It consists in equipping the locomotive, for instance, with a small electric motor, set on top of the boiler between the steam dome and sand box, and having levers connecting with the handles of the brake, throttle and sand box. The motor is in circuit with a local battery conveniently situated in the cow-catcher, and introduced in circuit with the motor by the magnet also seen in the cow-catcher. This magnet is in an open circuit with a generator on the last car of a second train, and with generators at the bridge, switch or crossing. At predetermined distances these generators will become closed through the magnet, on account of the provision of double sectional conductors extending along the track. One of these conductors is in permanent connection with the magnet, while the other joins the generator in the last car of a second train, or at a switch, etc. The remaining terminals of the magnet and generators have permanent connections with the rails which serve as ground returns.

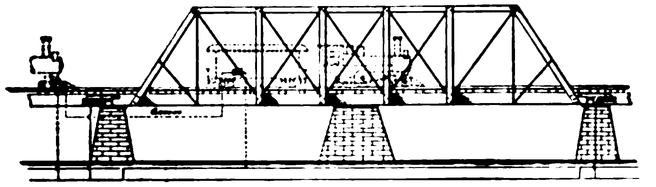

Fig. 2.

From what has just been described, it is evident that upon the approach of two locomotives within the predetermined distance, the circuit will be closed and the motor on the locomotive at once be started to close the throttle and apply the brakes automatically. The system thus makes the engineer independent of all signals and increases the safety of travel accordingly.

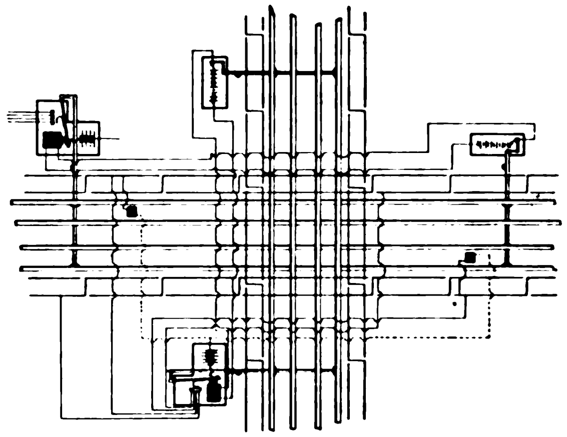

Fig. 3.

ELEMENTARY GEOMETRICAL THEORY OF THE ALTERNATE-CURRENT TRANSFORMER.—I.

BY

Chas. Steinmetz.

Introduction.

Since the alternate current system is coming more and more into general use for electric light and power distribution, the alternate current transformer, or converter, as the most essential part of this system, has gained an importance, which but a few years ago nobody would have expected, to judge from its experimental predecessor, the induction coil.

But, since at present all mathematical and analytical theories, especially if they have to start from the solution of differential equations, are still of very little value for the "practical engineer," who is not yet generally expected to master the powerful weapons of mathematics, it may be considered of some interest, if in the following I try to give an explanation of the fundamental phenomena met with in transformers, so far as they are of importance for the designing and working of alternate-current transformers, and of some phenomena, which, although found less often in transformers, are generally noticed by their destructive effects, such as oscillating discharge, some effects of static capacity, etc. I propose to show this in a way which presupposes no higher mathematical knowledge than the acquaintance with the sine-function, and perhaps the elements of infinitesimal calculus. The application of the diagrammatical method will be found equally adapted for the treatment of other alternate current apparatus, although the limited space available does not allow me to enter deeper into the consideration of apparatus other than transformers.

Indeed, I do not at all claim to be the first to use graphical representations of alternate current waves, but many applications of similar methods can be found in the publications of Kapp and others, and especially in Blakesley's.

But so far as I know they all represent the instantaneous values of the current, the E. M. F., etc., by the projections of a line $\overline{OX}$ upon the centre line $\overline{OA}$, the line $\overline{OX}$

representing the maximum value of the current, etc., and giving by one revolution around the centre O the time of one complete period. This representation has the disadvantage of giving the instantaneous values of the electric or magnetic quantities not on the variable radius which represents the time, but all on the line OA, and therefore does not show so well the relative magnitude of different quantities; it fails especially to give a characteristic curve which allows us to survey the whole change of the periodic function at once; besides, it can be used conveniently only for true sine-waves. We shall in fact restrict ourselves generally to the consideration of true sine-waves, and also show the action of other shapes of electric waves only occasionally.

But in reality the currents of our modern alternators differ from true sine-waves only slightly, and self-induction and mutual induction have the tendency to make the shape of the current wave still more sinusoidal. Therefore, in supposing a true sine-form we will approximate the real actions in alternate current apparatus at least very nearly, and may be allowed to treat the differences caused by a differing shape of the wave only as correctional terms of secondary order.

Of fundamental importance is the law, that several sine-waves always combine into sine-waves again, are always induced by sine-waves, and induce sine-waves; indeed, waves with a shifted phase.

Therefore:

"*If the primary* E. M. F. *of a transformer follows the sine-law, all the* E. M. F'S. *currents and* M. M. F'S.[1] *must follow the sine-law also.*"

The only phenomenon, which, when heavy self-induction is present, is apt to change the sinusoidal shape of the current wave—the E. M. F. being a true sine-wave—is *hysteresis.*

But here experimental tests show, that in almost all cases, the influence of hysteresis can be replaced by a current of the same phase as the induced E. M. F., which current, by its effect, represents the energy expended in the reversals of magnetism. Then hysteresis is also represented by a sine-wave.

As an example for showing the application of the *polar-diagram of alternate currents*, let us consider a transformer, which is intended in its secondary circuit to give an E. M. F. of 70.7 volts, effective.

Then the maximum E. M. F. of the secondary circuit is:

$$E_1 = 70.7 \times \sqrt{2} = 100 \text{ volts.}^2$$

Let the number of complete periods per second:

$N = 133$ (ordinary incandescent-light dynamo frequency), so that, $T = .0075$ second is the time of one complete period.

From this we get the maximum intensity of the "*magnetic current*," necessary to induce the maximum E. M. F. of 100 volts.

For, let the number of primary turns: $n = 80$;

" " " secondary " : $n_1 = 60$.

Then the maximum E. M. F. induced in the secondary by the magnetism M is:

$$E_1 = 2\,\pi\,N\,n_1\,M \text{ (C. G. S.) units, or:}$$

$$E_1 = 2\,\pi\,N\,n_1\,M \times 10^{-8} \text{ volts.}^1$$

This being equal to 100 volts, we derive:

$$M = \frac{E_1 \times 10^8}{2\,\pi\,N\,n_1} = \frac{100 \times 10^8}{2\,\pi \times 133 \times 60} = 200{,}000 \text{ lines of}$$

magnetic force.

We have to choose now the *maximum magnetization, or maximum magnetic field intensity, H,* at which we want to work the transformer.

If we use a high field intensity, for instance $H = 40{,}000$ or 50,000 lines of magnetic force per square inch, we need only a small cross section of iron. Thence the length of the convolutions of the copper wire become shorter, and thereby the *loss of energy in the copper* smaller.

This not only affords a saving of material and of energy in the copper, but also a better compounding of the transformer, so far as the electric part of it is concerned, because the drop of potential for full load decreases with the decreasing internal resistance.

On the other hand, with the increasing field intensity the *loss of energy in the iron*, due to *hysteresis and eddy currents*, increase faster than the field intensity, so that, if we double the field intensity, although we are able then to halve the iron cross section, nevertheless we shall find the whole amount of the iron loss essentially increased; because for twice the magnetization the iron loss per cubic inch is more than doubled, being about 3½ times as high, and therefore the whole expenditure of energy in the iron about 1¾ times its former value; so that this increased iron loss might more than counterbalance the gain by the saving of energy in the copper, and the greater "magnetizing current" (termed "resulting M. M. F." in the following) needed for the production of the magnetism makes the compounding of the converter still worse.

The *loss of energy due to hysteresis* proper in the iron, besides being directly proportional to the number of periods used, seems to be nearly proportional to the 1.6th power of the magnetization, as I have already calculated[2] from observations made by Ewing, and as my own tests made subsequently seem to prove:

$$H = A\,B^{1.6} \times N.$$

The *loss of energy due to eddy-currents* in the iron must be very nearly proportional to the square of the magnetization, and proportional to the *square* of the number of periods used:

$$\Lambda = \varepsilon\,B^2 \times N^2.$$

Hence, the loss by eddy-currents will be more perceptible than the hysteretic loss for higher magnetization and greater number of periods; but very small for low magnetization and small number of periods. Then the iron loss will consist mainly of static hysteresis.[3]

Eddy-currents can hardly be avoided. I do not think that they circulate as much in the thin iron laminæ themselves, but that they find an easy circuit from lamina to lamina through the whole length of the iron. At least in all the (commercial) transformers, and in a number of other laminated electromagnets, which I had occasion to test for it, I found electric connection through the whole pile of iron laminæ, such a good connection, that I could not even determine its resistance, without going into more complicated measurements. Therefore the losses in the iron must be expected to increase with a higher power than 1.6, and a lower power than the square of the magnetization.

---

1. In the same way as we use "E. M. F.," I shall in the following abreviate *magnetomotive force* (measured by ampere-turns) to "M. M. F."

2. If: E_1 = the maximum E. M. F., we have:

$$e_1 = E_1 \sin \frac{2\,\pi}{T}\,t = E_1 \sin 2\,\pi\,N\,t,$$

the instantaneous value of the E. M. F. at the time, t;
where T = the time of one complete period, or:
N = the number of complete periods per second,

$$e_1^2 = E_1^2 \sin^2 2\,\pi\,N\,t.$$

The square thereof,

$$N\int_0^T E_1^2 \sin^2 2\,\pi\,N\,t\,d\,t = \frac{N\,E_1^2}{2}\int_0^T \{1 - \cos 4\,\pi\,N\,t\}\,d\,t = \frac{N\,T\,E_1^2}{2} = \frac{E_1^2}{2},$$

the mean square of the E. M. F., and:

$$\frac{E_1}{\sqrt{2}},$$

the "*square root of the mean square*" or the "*effective*" E. M. F.

1. The "magnetic current" at the time t is:

$$m = M \sin 2\,\pi\,N\,t; \text{ where, } M = \text{maximum magnetism.}$$

Therefore the E. M. F. induced in the secondary circuit:

$$e_1 = -n_1\,\frac{d\,m}{d\,t} \times 10^{-8} = -n_1\,M\,2\,\pi\,N \cos 2\,\pi\,N\,t \times 10^{-8} \text{ volts,}$$

hence a maximum, E_1 for: $\cos 2\,\pi\,N\,t = -1$; $t = \frac{1}{2\,N} = \frac{T}{2}$, and

$$E_1 = 2\,\pi\,N\,n_1\,M \times 10^{-8} \text{ volts.}$$

2. See "Note on Hysteresis," THE ELECTRICAL ENGINEER, Dec. 17, 1890.

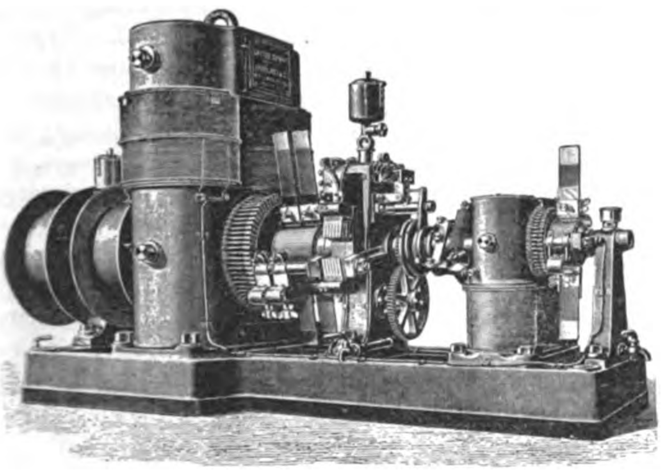
3. This gives a very convenient way to separate the true hysteretic loss from the loss due to eddy currents, by determining the loss in the iron for different frequencies, or for different magnetic intensities.

For well-insulated magnets, and the usual number of alternations, I found the assumption of an increase of the iron loss proportional to the 1.7th power of the magnetization (field intensity) generally pretty near the real facts; near enough at least to be used in designing new work. In three more complete sets of tests I found the iron loss fairly well proportional to the 1.68th, 1.70th and 1.925th power of the field intensity, for 100 complete periods per second. In the third case, no paper insulation was used between the iron laminæ.

HOLMES' TRAIN LIGHTING DYNAMO.[1]

Many attempts have been made to light trains electrically, the chief difficulty being in the variation of speed of driving the dynamos. Separate engines have been used, but have been found unsatisfactory. We illustrate a solution of the problem, due to the ingenuity of Mr. J. Holmes, of Newcastle. The inventor explains his dynamo as follows:

Practically the E. M. F. of an ordinary separately excited dynamo varies directly as the speed, so if the speed be increased, say, from 500 revolutions per minute to 1,000 revolutions per minute, the electromotive force will be doubled. The electromotive force varies directly as the strength of the magnetic field, so that, if the strength of field of a separately excited dynamo be reduced in the same proportion as the speed at which its armature revolves be increased, the electromotive force of the armature will remain practically constant.



Holmes' Train Lighting Dynamo.

To produce this result two dynamos are arranged having their armatures upon the same shaft, so as to revolve together, but influenced by separate magnetic fields. One is the main generating machine, the other is for regulating the strength of its magnetic field. The magnets of the machines are separately excited from an external source, such as a set of accumulators, and the magnets of the generating armature are provided with two distinct exciting circuits. One circuit is an ordinary high resistance shunt circuit, and the other is of less resistance, and is coupled up to the source of current so as to have the small regulating armature in series with it. The regulating armature is so coupled up that its electromotive force opposes the electromotive force of the regulating armature and external source of supply. The high resistance shunt circuit is so proportioned that, at the highest speed at which it is intended to run the generating armature, it, without the aid of the regulating circuit, will give a magnetic field of an intensity proper for the required E. M. F. in the generating armature. When thus driven, the second exciting circuit ought to have no current passing through it, and this is secured by making the E. M. F. of the regulating armature at its highest speed equal, and opposite, to the external source of E. M. F. produced in the second coil of the generating machine. If, however, the speed falls, the E. M. F. of the regulating armature is reduced in the same proportion, and is no longer equal to the external E. M. F., and a current will flow through the second exciting circuit of the magnets of the generating dynamo, thus increasing the intensity of the magnetic field to make up for reduction of speed, maintaining a practically uniform E. M. F.

The armature is driven by belting from the axle of the guard's van, and a set of accumulators excite the field magnets. A centrifugal governor automatically switches the storage batteries in or out. The brushes which collect the current from the two armatures are made of wire gauze, and are placed radially, the "lead" being automatically altered to suit the direction of rotation. The connections to the armature are changed at the same time.

This dynamo is used by the Midland Railway Company for their express trains, and has also been applied to French, German, and Russian railways.

CATAPHORIC MEDICATION.

At the recent ordinary meeting of the Society of Arts, says our London correspondent, Mr. W. Preece, F. R. S., presiding, Mr. H. Newman Lawrence read a paper on "Electricity in Relation to the Human Body," the joint production of himself and Mr. Arthur Harries, M. D. After glancing at the increased importance of the subject at the present day, when electrical apparatus is so largely employed, the authors observed that it possessed little or nothing of a history, and they proposed to deal with it mainly in the light of their own experiments and observations. It naturally divided itself into two parts, the one, possible dangers to the body, and the other, possible advantages.

The advantages of electricity to the human system far outweighed its dangers, and these were the subject of the second portion of the paper. It noticed the fact that atmospheric electricity is apparently the cause of the transformation and retransformation of oxygen into ozone, and ozone into oxygen passing through a cycle of changes, commencing with atmospheric electricity and ending with electrical currents within the body. The uses of electricity in disease were numerous and valuable, and they were steadily on the increase. After taking note of some of these, it entered into explanations of the new and important branch of the subject known as "Cataphoric Medication," or the process of passing drugs in solution by means of the cataphoric power of electric currents. Little or nothing was actually known on this subject when the authors began a course of experiments upon it in the Autumn of 1889, and the results of these had been so promising that they proceeded to use it as a method of treatment in actual disease. A demonstration of the method was given in the course of the lecture, but this was preceded by a description in outline of the initial experiments, which were described by Dr. Harries with aid of the blackboard. In the first, two glass vessels were taken. The one was nearly filled with dilute sulphuric acid, the other with a solution of barium chloride. The two vessels were then connected by a piece of lamp wick soaked in a solution of salt, which dipped into the contents of each. After waiting twenty-four hours there was no trace of the chemical action, which might have been expected to ensue in consequence of the connection of the two by the lampwick, but on two electrodes being inserted in the fluids, connected with a battery, and a current of 100 milliamperes being sent through the whole, a precipitation of barium chloride was seen after the lapse of half an hour. The second experiment was a slight advance on the first. A porous septum divided the two solutions, and which were of iodine and starch, respectively, and a small quantity of iodide of starch was formed in the same way. In the cataphoric power of electrical currents the same principle was in operation, the only change being that in place of a porous septum the skin was used, and it could be shown in the trial about to be made of the method in which a solution of cocaine, which was an anaesthetic, would be passed through the skin, that the patient was entirely free from pain during the process. The experiment was then performed, and the operator then inserted a platinum needle, connected by a wire with a handle attached to a galvanic battery, one-sixteenth of an inch below the surface. The patient remained perfectly calm under the process, and the thoroughness of the action was seen in the fact that one or two hairs had been loosened, and were readily removed, the needle having passed into the follicle at the base, in each trial. In answer to numerous questions, Dr. Harries explained that cocaine alone would have produced only a small effect, and that which was seen was really due to the cocaine and the electricity jointly.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. XI. NEW YORK, JUNE 3, 1891. No. 161.

Honor those who seek knowledge for her own sake, and remember that they are the great heroes of the world, who work in faith, and leave the result with God.—Josiah Parsons Cooke.

THE RAPID TRANSIT REPORT.

IT is impossible to be other than very well pleased with the report of the New York Rapid Transit Commission, which is printed in our columns this week. As will be seen, this report, in dealing with the questions of rapid transit for the West Side of this rapidly growing city, proposes an underground four-track road, with electricity as a motive power, two of the tracks being devoted to express service and two to way trains. We are glad to see that the report has been well and warmly received, the only adverse criticism coming from such interested quarters as the *Sun*, which makes itself the mouthpiece of the Elevated Railroad Company.

The engineers of the Commission are to proceed at once to the perfection of plans for the road, while the Commission itself deals next with the waiting problems of the East Side. The estimate of outlay for the road to run from South Ferry to the City Line on the west is about $40,000,000, and the Commission have assurances from capitalists that the amount can be easily raised. There should be no reasonable doubt as to the success of the road as a paying investment. The route lies through a thickly populated district, whose needs are well indicated by the fact that the traffic of the elevated system increased by nearly 75,000,000 passengers between 1886 and 1890, and that in the meanwhile the Broadway horse car service came into operation to carry many millions annually, and to pay handsome dividends. Moreover, from the fact that the road will place Harlem within 12 minutes of the City Hall, it will develop a new and enormous traffic of its own, and preempt the whole of the vast semi-suburban region between Eighth avenue and the Hudson and Grant's Tomb and Yonkers, which hitherto has not enjoyed a service distinctively its own, and has not the remotest idea of the real meaning of rapid transit. Electrical engineers should congratulate themselves that to them the larger portion of the population of New York is now looking for swift and safe travel between home and work.

THE DESIGNING OF ALTERNATING CURRENT APPARATUS.

ALTERNATING current apparatus of various types has now been in practical operation a sufficient length of time to afford an abundance of data upon which to base tolerably accurate calculations, and as time goes on constructors will be facilitated in their work by the successful practice of improved methods. But as it is the living present which most concerns the electrical engineer, he naturally looks about for the methods nearest at hand, and in the most convenient form. The graphic method has proved of great assistance in solving mechanical engineering problems, and in the design of electrical machinery the advantages possessed by this method were also early recognized. To promote the study of alternating current apparatus by the graphical method, we begin, in this issue, a valuable series of articles by Mr. Charles Steinmetz, in which, basing his determinations upon the results of actual experience, he shows how the data at hand can be employed in the designing of the most efficient apparatus. Although this method has been employed before, its use has been limited to but a comparatively few cases. Mr. Steinmetz's articles, however, will treat the problem in a way which will be generally applicable, while at the same time giving examples showing the method of applying this system of designing to particular cases.

WORLD'S FAIR NEWS.

IT is now definitely understood that the recently proposed solution to prevent an extended division of the electrical exhibit, will be adopted. By this plan, which, under the conditions, is excellent, and appears to be the best practicable method, all the generating plant will be placed in a portion of the Machinery Annex, occupying as much space there as required, and the necessary electrical energy will be furnished from there to the Electricity Building, and to all parts of the Exposition. The placing of all the various electrical generators, and the power machinery operating them, together in the Machinery Annex, will form a vast and most interesting exhibit of the various systems of producing electrical energy, and will be, to all intents and purposes, part of the electrical exhibit forming an annex to the Electricity Building.

The Electrical Department and the Construction Department, of the World's Columbian Exposition, are working together in perfect harmony, and all differences of opinion have now been happily settled by the aforesaid excellent solution of the main points of contention, and the good work will now go on rapidly and vigorously to completion

The employment of electrical energy for every conceivable purpose in every part of the Exposition, will be carried out in the most extensive manner, and it will be found on all sides furnishing lighting, heating, power and traction; making an unparalleled display and demonstration of the marvelous adaptability of electricity.

Prof. Barrett, Chief of the Electrical Department, is working strenuously to bring about a magnificent exhibit and satisfy the electrical people in every particular, and Mr. Frederick Sargent, the electrical engineer of the Construction Department, is pushing matters along with the utmost dispatch, to carry out the requirements of Prof. Barrett.

STANDARD CELLS.

It is with pleasure that we accord space in this week's issue to a communication on standard cells by Prof. H. S. Carhart. This communication is called forth evidently by our editorial remarks on the type of standard cell recently described by Mr. Carl Hering before the Franklin Institute and reproduced in our pages. We are in perfect accord with Prof. Carhart's advocacy of the Clark cell as prepared under the directions given by Rayleigh, and believe that its constancy is as nearly perfect as can be obtained in a standard of this type. But in our remarks above referred to we drew attention to the fact that what was wanted was a standard "*simple in construction* and permanent in its indications under all conditions." Granted that the Clark cell is sufficiently permanent in its indications for all practical purposes, we believe that the difficulties of procuring the pure materials necessary for its construction will always be a bar to its general or universal employment, and hence it does not fulfill the dual conditions above quoted. Those conditions must be the attribute of every "standard" in order to secure its universal utilization. Meantime, there will, of course, be more and more use for the standard cell for many years to come. The thing to replace it has not yet made an appearance.

ARMATURE REACTION IN CONSTANT CURRENT DYNAMOS.

The study of the dynamo electric machine has in the past been largely concentrated on the constant potential type of machine, with the result that there is comparatively little which the student or constructor finds available when he essays the designing of constant current machines. The small magnetic strength of the armature, which forms the characteristic of constant potential machines, makes the question of armature reaction of lesser importance, but the enhanced magnetic value of the constant current armature, as compared with that of the field magnet, makes the reaction of the constant current armature enter as an important factor in the operation of the machine.

In discussing this feature in a recent paper read before the Chicago Electric Club, Prof. H. S. Carhart, after referring to the nature of the characteristic curve required in a properly acting constant current machine, held that so far as the direct influence on the field is concerned, the nature of the armature reaction is referable to two quite distinct factors. The currents circulating round the armature reduce the magnetic flux both by increasing the magnetic resistance or equivalent length of the magnetic surface and by generating a counter magneto-motive force. The former is affected in just that portion of the circuit where the resulting change is the greatest, that is, in the air interspace adjacent to the polar faces. The other factor appears to play a much more important part in regulation by motion of the brushes than the deformation of the field at the polar tips; for by means of it the brushes may be kept nearly sparkless from full load to short circuit. That the magneto-motive force, having its origin in the ampere-turns on the armature, is inverse and not direct is evident from the fact that when the brushes were rocked forward the poles induced in the armature by the field are always of opposite sign to those produced by the armature currents. Hence these currents circulate in such a direction as to demagnetize the field.

To verify the correctness of his assumption, Prof. Carhart studied the reactions taking place in the armature by means of a third brush and measuring the potential differences between the main brushes and third brush placed at various points around the commutator. On the machine he experimented with, one of the first of the Gramme type constructed in this country, Prof. Carhart finds that if the total electromotive force of the generator remain constant, then, as with a battery, the increased current means increased loss of potential in the armature, and therefore a smaller difference of potential at the brushes; and if smaller at the main brushes it will be smaller between the point of derivation of the supplementary circuit.

His experiments also showed that, on account of the reaction of the armature, the region of the commutator on either side of a brush, or the armature coils in these positions, is a relatively weak field, the angular distance through which the potential rises to a maximum being nearly double that required to bring it down again to the level of the main brush.

The change of voltage in the third brush circuit, whenever the main current varies from its normal value, suggests to Prof. Carhart the practicability of utilizing this relation for the purpose of securing automatic regulation of the current, and he has tried this method with satisfactory success. The third brush circuit contained an electro magnet as a responsive device, and this served to bring into action either an electro magnetic motor or mechanical motor mechanism for rotating the brush holder.

Incandescent Lamp Economy.

Quite recently the marked decrease in the price of incandescent lamps served again to bring out prominently the laws which govern the highest economy attainable in this class of work; and in a recent issue we printed an excellent disquisition on the subject by Mr. H. Ward Leonard, who showed conclusively that with the lowering in price, lamps could be burned at higher efficiency, and hence with shorter life, and still prove more economical than the longer lived lamps. In this issue Mr. W. D. Weaver brings up to date the results of calculations made on this point a number of years ago, and which show that his early analysis was correct. His figures agree very well with those of Mr. Leonard and ought to be studied by every central station manager.

INCANDESCENT LAMP ECONOMY.

BY

W. W. Weaver

ASSISTANT ENGINEER, UNITED STATES NAVY.

SOME years ago the writer published,[1] under the above caption, the results of a mathematical investigation into the commercial efficiency of incandescent lamps (probably the first that appeared in print), and as the subject is now one of increasing importance, a *résumé* may be of interest, particularly as recent data permit more accurate deductions to be made.

An investigation of numerous lamp tests showed that the curves of the variation of candle power with the energy furnished the lamp were of the form, $C E = k_1 x^n$, where C = current, E = E. M. F., and x = c. p., and the value of the constant n was found to be 2.85, which the data of subsequent tests have verified. The value of n from all tests varied little, while in the formula $C = k x^n$ the variation was considerable.

The result of elaborate experiments to determine the variation of the life of a lamp with the c. p. at which it is used was communicated to the writer as being expressed by the equation $l = \frac{k_2}{x^m}$ which relation held true "for even the widest ranges of c. p.," the value of m being given as 3.65.

From these two, and other relations given below, the following formulæ were deduced, the notation being as follows:

a = entire cost of one h. p. per hour delivered at the lamp, depreciation of plant and interest on capital being taken into account.
b = cost of lamp;
x = c. p. of lamp;
y = entire hourly cost of unit light (one c. p.);
l = life of lamp;
C = current;
E = E. M. F.;
P = normal c. p. of a lamp;
W = watts per lamp at normal c. p.;
L = life of lamp at normal c. p.

Then,

$$\frac{b}{l\,x} = \text{hourly } lamp \text{ cost of one c. p.}$$

$$\frac{C\,E}{746} \times a \times \frac{1}{x} = \text{hourly } energy \text{ cost of the same.}$$

$$\therefore\ y = \frac{b}{l\,x} + \frac{a\,C\,E}{746\ x} \quad - \quad - \quad - \quad - \qquad (1.)$$

Substituting for $C\,E$ and l their values from the equations $C\,E = k_1 x^n$ and $l = \frac{k_2}{k^m}$ and reducing,

$$y = \frac{b}{k_2} x^{m-1} + \frac{a\ k_1}{746}\ x^{\frac{1-n}{n}} \quad - \quad - \quad - \qquad (2.)$$

Differentiating and placing $\frac{d\,y}{d\,x} = 0$, we have for the value of x at which y is a minimum:

$$x = \sqrt[\frac{m\,n-1}{n}]{\frac{a\ k_1\ k_2\ (n-1)}{746\ b\ n\ (m-1)}} \quad - \quad - \quad - \qquad (3.)$$

Substituting for k_1 and k_2 their values $\frac{W}{P^{\frac{1}{n}}}$ and $L\,P^m$ respectively, we have the final general expression,

$$x = P \times \sqrt[\frac{m\,n-1}{n}]{\frac{a\ W\ L\ (n-1)}{746\ b\ n\ (m-1)}} \quad - \qquad (4.)$$

Taking $16 = P$ as the normal c. p., and m and n 3.65 and 2.85, respectively, we have finally,

$$x = 1.4 \sqrt[3.3]{\frac{a\,W\,L}{b}},\ x = 1.4 \sqrt[3.3]{\frac{a\ W\ L}{b}}, \qquad (5.)$$

From equation (5.) Tables I. and II. have been calculated. In the first table it is assumed that the cost of the lamp is 40 cents, and in the second table, 60 cents. The figures in the first column are the watts with which the unit light is produced at the normal c. p. (16); the cost of the hourly h. p. is given in the second column in cents, and is the entire cost of an electrical h. p. delivered at the lamp, interest on, and depreciation of, plant being included; the life of the lamp at the normal c. p. is given at the head, and the remaining figures are the respective c. p.'s at which the cost of the unit light, under the conditions given, is a minimum.

CANDLE POWER AT WHICH COST OF UNIT LIGHT IS A MINIMUM.

TABLE I.

Cost of lamp = 40 (b).

Watts per c. p. $\left(\frac{W}{16}\right)$	Cost of hourly h. p. (a).	Life of lamp (L). Hours.		
		600	800	1,000
	1	10.4	11.4	12.2
3.1	3	14.6	15.9	17.0
	5	17.	18.5	19.9
	1	11.	12.	12.8
3.7	3	15.3	16.7	17.9
	5	17.9	19 6	20.9
	1	11.3	12.4	13.2
4.1	3	15.9	17.3	18.5
	5	18.5	20.2	21.6

TABLE II.

Cost of lamp = 60 (b).

Watts per c. p. $\left(\frac{W}{16}\right)$	Cost of hourly h. p. (a).	Life of lamp (L). Hours.		
		600	800	1,000
	1	9.2	10.	10.7
3.1	3	12.8	14.	15.0
	5	15.	16.4	17 5
	1	9.7	10.6	11.3
3.7	3	13.5	14 8	15.8
	5	15.8	17.3	18.5
	1	10.	10.9	11.7
4.1	3	14.	15.2	16.3
	5	16.3	17.9	19.1

Tables III. and IV. were calculated by means of equation (2.) and Tables I. and II., and show the relative minimum cost of the unit light under the conditions given; or, in other words, if the filaments of the lamps represented by the figures in Tables I. and II. were burned at the incandescence necessary to produce the c. p.'s as deduced, but lengthened or shortened so as to all give a uniform quantity of light, 16 c. p., say, the figures in Tables III. and IV. show the relative minimum cost of the light.

RELATIVE VALUES OF MINIMUM COST OF UNIT LIGHT.

TABLE III.

Cost of lamp = 40 (b).

Watts per c. p. $\left(\frac{W}{16}\right)$	Cost of hourly h. p. (a).	Life of lamp (L). Hours.		
		600	800	1,000
	1	11.0	10.4	1.00
3.1	3	25.7	25.2	24.1
	5	40.3	38.0	36.5
	1	12.7	12.0	11.6
3.7	3	30 6	29.0	27.8
	5	46.4	43.8	42.0
	1	13.8	13.0	12.5
4.1	3	33.4	31.5	30.2
	5	50 4	47.6	45.6

TABLE IV.

Cost of lamp = 60 (b).

Watts per c. p. $\left(\frac{W}{16}\right)$	Cost of hourly h. p. (a).	Life of lamp (L). Hours.		
		600	800	1,000
	1	11.9	11.3	10.8
3.1	3	28.9	27.3	26.1
	5	43.6	41.2	39.5
	1	13.7	13.0	12.4
3.7	3	33.3	31.5	30.0
	5	50.2	47.4	45.4
	1	14.9	14.1	13.5
4.1	3	36.2	34.2	32.7
	5	54.6	51.5	49.4

---

[1] THE ELECTRICAL ENGINEER, April and September, 1885.

These latter tables show several interesting facts. For example, accepting the constants given, when lamps are used under the necessary conditions to give the minimum cost, the 40 cent lamp with a life of 600 hours is as efficient as the 60 cent lamp with a life of 1,000 hours, while, with an equal life, the 4.1 watt 40 cent lamp is as efficient as the 3.7 watt 60 cent lamp. If the same constant could be accepted, deductions similar to those made for Tables I. and II. would fix the length and incandescence, approximately, that should be given to a filament.

Unfortunately, however, the value of the constant *m*, as given, was determined for only one kind of a lamp, so that its value can only be provisionally accepted. On the other hand, equation 4 remains true and should prove of considerable practical value when this constant has been determined to some degree of exactness.

THE FUTURE OF THE ALUMINUM PROBLEM FROM THE CHEMICAL STANDPOINT.[1]

BY DR. WM. H. WAHL.

Dr. Wahl began with an interesting discussion of the chemical reactions in the metallurgical method of reducing aluminum, with special reference to the processes of Deville-Castner, and Netto. Speaking, then, of the electrolytic method, he continued:

On the basis of these facts and inferences let me present you with an interesting comparison. I will employ to this end the deadly parallel columns, with full knowledge of the risk of handling so dangerous a weapon.

Capt. Alfred E. Hunt, in a lecture recently delivered before the Boston Society of Arts, gave the following estimate of the probable cost of manufacturing aluminum by the electrolytic method practiced by the Pittsburgh Reduction Company, of which he is the head. This estimate is based on the assumption that the manufacture shall be conducted on a scale of much greater magnitude than at present and with the cheapest source of power, namely, water power. *Apropos* to this estimate of Capt. Hunt, I wish to remark that it has afforded me a most interesting subject for study, and I desire here to declare my conviction that it is in no single item exaggerated on the side of economy. Respecting one of the figures named—that of the cost of water power—I entertained at first some doubts as to its accuracy, and to satisfy myself on the point I presented the inquiry to my friend, Prof. Coleman Sellers, an engineer of wide experience and at present one of the Board of Consulting Engineers to the Cataract Construction Co., which is engaged in the important work of utilizing on a grand scale the water power of Niagara Falls. I will take the liberty of quoting to you from a letter which I received from him some data covering the subject of my question:

"Almost all the existing examples of water power are dependent upon accumulation of water in reservoirs created by erecting dams across existing rivers and so accumulating water and distributing it by canal to the water wheels, as at Holyoke, Lawrence and our own Schuylkill river. The water power, for instance, of the Schuylkill, and sold by the Schuylkill Navigation Co., was quite limited in its amount and is already exhausted, and it may be assumed to be somewhere in the neighborhood of $30 or $35 per horse-power per annum, for day use only. These water powers are generally sold either by day use or by 24 hour use, and for the purpose of metallurgical reductions it would probably be required on the 24 hour basis.

"The difficulty about getting at the cost of these water powers is the uncertainty of the continuance of the dams that are built to retain the water. These are liable to decay and deterioration and sudden freshets often destroy them entirely, involving heavy costs that are not known until the event occurs. The exceptional case of Niagara presents an absolutely unfailing water power that does not vary the year round. The difficulty in the way of its use, however, consists in the extreme width of the breast of the dam and the necessity for carrying the water through a long surface canal to the lower chasm where it is to be used, or the digging of the tunnel as a tail-race to carry away the water that has been used from the wheels or other motors.

"A canal was built about 40 years ago which is still in use, that carries about 6,000 horse power to the lower river, but this amount of power has already been more than exhausted by users who availed themselves of it, and its further extension by that method would be very costly. The present scheme of utilizing Niagara Falls by the company in which I am interested, is by means of a tail-race tunnel under the town of Niagara, and the preliminary work now being done, when completed, in about a year, will throw into the market about 120,000 horse power that may be said to be absolutely permanent and endurable and capable of being worked for 24 hours in the day. It is premature to say what this power will bring in the market, but it is the only example I know of where water power can be counted on as absolutely staple and not liable to any disturbance or delay, and where the price will be comparatively low. I should think that you might safely say that it presents the possibility of power being obtained at less than half of what it would cost in any other known case, taking into consideration all contingencies. Small amounts of power may be obtained from streams of water of a reasonable degree of stability and far away from existing markets, as low probably as $4 or $5 per horse power per annum, but this is subject to the risk before mentioned.

"It is not alone the mere cost of water power that must be considered, but in a case like this it is the continuance or permanency of the power that will give it its value and that power will be the most valuable that is liable to the least fluctuations either in quantity or cost. I do not think, however, that it will be safe for you to predicate the value of metal produced upon anything short of about $15 per horse power per annum, for 24 hour power, and that in very large quantities, while perhaps $20 per horse power per annum would cover all contingencies."

Taking the estimate of $20 per horse power per annum as sufficient "to cover all contingencies," we would have as the cost of one horse power per hour 0.238 cent (or, say, about one-fourth of a cent.

This would give for 22 h. p. 5¼ cents, and for 22 electrical horse-power, allowing 10 per cent. for loss in the conversion, 6 cents. Capt. Hunt allows 5 cents for his power, which, considering that the figure named by Prof. Sellers is obviously intended to be liberal, I feel satisfied is a fair one. This item of Capt. Hunt's estimate is the only one respecting which I have at any time entertained any doubts, and I have been so impressed in reading his admirable lecture, with the carefulness and accuracy of his statements, and his evident desire to avoid any suspicion of exaggeration, that I am quite prepared to accept the other figures, which are based on the experience gained in the practical working of company's plant.

Capt. Hunt's estimate of the capabilities of the electrolytic method of producing aluminum on the largest scale is as follows:

BY THE ELECTROLYTIC METHOD.

COST OF PRODUCING ONE POUND OF ALUMINUM.

2 lbs. alumina (containing 52.94 per cent. Al_2) at 3 cents	.06
1 lb. carbon electrodes, at 2 cents	.02
Chemicals, carbon dust and pots	.01
22 H. P. for 1 hour (water power)	.05
Labor and superintendence	.03
General expense, interest and repairs	.03
	$.20

BY THE METALLURGICAL METHOD.

COST OF PRODUCING ONE POUND OF ALUMINUM.

3¼ lbs. Al_2F_6 (containing 32. 7 per cent. Al_2), at 3 cents	.09¾
2½ lbs. sodium, at 3½ cents	.09
Labor, superintendence	.03
General Expenses, Interest and repairs	.03
Total	$.24¾

The fundamental fact that alumina can be reduced to the metallic state by carbon, is established. It is proved beyond peradventure by the operation of the electric furnace of the Cowles Bros., in which heat, developed by the transformation of electric energy upon the passage of the electric current through a fragmental resistance material of carbon and alumina (with copper or other metal present as a solvent), is believed to be the principal agency in effecting the reduction. The same action may probably take place, to some extent, in the operation of the Heroult furnace, and certainly so, if the statement can be verified that the output of this furnace is greater than can be accounted for by simple electrolytic action.

The reduction of alumina by carbon, therefore, may safely be stated to be simply a problem of temperature, and this temperature is probably not far above the fusion point of alumina. This, unfortunately for the practicability of the direct reduction process, lies enormously high, so high, indeed, that it does not admit of instrumental measurement, but can only be approximately estimated as somewhere between 2,000 and 2,600 C.; a point which cannot be reached save by the intervention of electric heating.

There is an alternative, however, that offers a ray of hope to the chemist. There are other methods besides that of fusion for obtaining alumina in the state of a liquid. We have, at least there are very good reasons to believe that we have, solvents for alumina, and if the condition of fluidity is as important a factor as it is believed to be in inducing chemical reactions, we have the possibility open to us of establishing conditions favorable to the reduction of alumina by carbon, at temperatures perhaps far below the fusion point of alumina.

The fluorides of the alkalies and the alkaline earths, we have reason to believe, dissolve alumina freely, and there are other compounds into which alumina enters that may be dissolved in the proper menstrua.

---

[1] Abstract of a paper read at the General Meeting of the American Institute of Electrical Engineers, May 21, 1891.

Briefly summarized, the case stands thus :

The processes in which electricity is applied, either for the direct reduction of aluminum by electrolysis or as the agency for producing the heat required to effect its reduction by chemical reactions, have outstripped the metallurgical methods in the race for supremacy and have taken a decided lead.

Within the past two years the metallurgical processes as represented by the improved methods of Castner, Netto, Grabau, and others of less renown, have been forced to abandon the field to the electrical methods of Hall, Minet, Cowles and Heroult.

REPORT OF THE NEW YORK RAPID TRANSIT COMMISSION IN FAVOR OF THE UNDERGROUND ELECTRIC ROAD.

THE Rapid Transit Commission has filed the results of its labors in the following :

Resolved, That after a thorough investigation, it is the sense of this board that any additional rapid-transit system for the city of New York should embrace the following essential features :

1. That it should be such as to provide not only for present needs, but also be susceptible by additions, and not by radical changes or alterations, of such expansion as the future growth of the city may require.
2. That it should provide for express trains at high speed for long distances and for way service for intermediate distances upon separate tracks so located as to facilitate at proper intervals an exchange from express to local and from local to express trains.
3. That the surface of the streets and avenues in the city should be obstructed to the least possible extent, and that wherever surface ground is required private instead of public property should be used, if practicable.
4. That the first lines of railway to be constructed should be on or near the important thoroughfares, coincident—or as nearly so as possible—with the main arteries of travel.

Resolved, That, as meeting these requirements in the manner most feasible for the west side of the city, this board hereby approves of a plan for an underground four-track railway under Broadway, from a point at or near South Ferry to Fifty-ninth street, thence under the Boulevard to a point at or near One Hundred and Sixty-ninth street (with such length of viaduct at and near Manhattan street as may be necessary), thence under Eleventh avenue, or under private property immediately to the west thereof, as may be found most convenient, to such point as the contour of the ground may determine ; thence by a viaduct across Spuyten Duyvil Creek, and by tunnel or viaduct to the city limits.

Resolved, That the general plan of construction from, at, or near South Ferry to near Forty-second street shall be either by double-decked tunnel, with two tracks upon each deck or four tracks on the same level, as may be found upon examination and survey most expedient, the whole to be at such depth below the curb line as not to disturb the surface or endanger building foundations ; from near Forty-second street north to be four parallel tracks upon the same level, as near the surface of the street as practicable when in tunnel, but not in open cut at any point.

Resolved, That the stations for such line of railway shall be upon property acquired for the purpose, and shall be provided with ample elevator capacity wherever the platforms shall be twenty feet or more below the curb line.

Resolved, That the motive power for such railway shall be electricity or some other power not requiring combustion within the tunnel.

Resolved, That the engineers of this board be and are hereby instructed to make the necessary surveys and prepare in detail the plans and specifications for such railway, and submit the same promptly to this board for its further action in finally determining a general plan for submission to the Common Council, in accordance with the provisions of the Rapid Transit act of Jan. 31, 1891.

The work of preparing plans, engineering details, &c., for the Common Council, has been entrusted to the distinguished civil engineer, Mr. William E. Worthen, and Mr. W. B. Parsons, as his assistant. Electrical talent will also be consulted. The Commission, having thus planned for rapid transit on the west side, will now take up the question of rapid transit on the east side.

ELECTRIC METERS.[1]

BY GEO. W. WALKER.

THE time has come for the central station companies to realize that they must supply the electric current in a more thoroughly commercial manner—that is, it must be sold, as other commodities are sold, by measure, weight, or its equivalent. To convince, however, an already skeptical public that the electric current can be measured with as great, if not greater, a degree of accuracy than the established and accepted methods of measuring gas, water, and steam, is no small undertaking. The fact remains, however, that we have to-day a number of electric meters which will measure the electric current more accurately and thoroughly than instruments adopted for similar purposes in other branches of business.

The author then described the various types of meters proposed, as well as those now in actual use, and continued :

The meters which have thus far been described all provide for measuring the amount of current consumed in a culminate manner, either by a series of dials or by ascertaining the amount of metal deposited on an electrode. Therefore any question as to the correctness of the result attained cannot be explained in detail. The gas meter is our legacy, and, strange to say, the efforts thus far made by inventors have been to produce a meter resembling the gas meter as much as possible, both in its appearance and operation. The meter which I will now describe is one with which I am the most familiar and which differs in its operation from any thus far brought to your attention.

It has been usual in testing any electric meter to place in the circuit with the same an ammeter for the purpose of proving the correctness of the meter's operation. Assuming this hypothesis to be correct, we have in the Walker meter the element of a test instrument, inasmuch as the meter consists principally of an ammeter which measures all the current passing and records, by photography, the various positions occupied by the ammeter needle. The use of photography in this case is to eliminate the element of friction in the meter. When I use the word photography I do not wish to imply that there are lenses or any of the necessary devices pertaining to the photographic art to contend with. The apparatus is simply so arranged that the ammeter needle point is represented by a speck of light and as the needle changes its position this point of light traces an image on the sensitive paper which is immediately behind the same. In other words, we are practically photographing the position of the ammeter needle during such time as it is being affected by the passing current, and the result is a continuous line marked upon the sensitized paper representing the fluctuations of the ammeter needle.

In detail the meter consists of an ammeter coil or solenoid, in which an iron wire in the shape of a nearly complete circle is placed as a core. The same shaft to which the circle or core of the ammeter is attached has also fixed thereto a light aluminum sector provided with a fine vertical slot, this slot representing the needle or pointer of the ammeter. Immediately behind this sector is a box which encloses a roll of sensitized photographic paper. The screen placed between the sector and the box has a horizontal slot before which the sensitized roll is made to pass.

The vertical slot in the sector is so arranged as to come at right angles with the slot in the screen, so that in whatever position it may be it will always allow a point of light to pass from the lamp which is enclosed in the meter on to the roll of sensitized paper.

Perforations in the screen representing the calibration of the instrument cause continuous horizontal lines to be printed on the sensitized paper. Another horizontal slot below these perforations is covered by a shutter which is opened every hour by the clock movement and causes vertical lines to be printed across the sensitized paper, representing hours of service. The number of the meter is also printed every hour just above this hour line. Means have been provided for causing a continuous movement of the paper roll at a given speed and this is effected by the use of a small clock movement which is wound automatically by the electro-magnet placed in shunt circuit with the lamp in the meter. The clock movement remains stationary and the lamp goes out when no current is on the circuit, but both start up immediately upon the lighting of a single lamp. In this way there is impressed upon the moving paper roll a complete record, in a detailed manner, of the current consumed in the circuit for a given time.

The roll of paper after a certain time, say one month, is taken from the box and developed in the usual manner, so as to fix the light impressions. It can then be measured up in the same way as an indicator card, by the use of the planimeter. The consumer is, therefore, at any time able to check the charges made, and the records being permanent can be used for future reference. It is evident that a large number of rolls can be developed in the same time required to handle a single one ; in fact, the number is restricted only by the size of the vessel used. In the meter, as at present manufactured, each square inch on the diagram represents sixteen ampere hours, therefore the total number of square inches measured by the planimeter need only be multiplied by sixteen to arrive at the sum total of the energy consumed. The loss in operating this meter is confined to the energy required to burn one lamp in the meter, which, at the candle power used, takes one-sixteenth of an ampere. This is the maximum loss whether the current of one, or one thousand, lamps is being measured, the ratio of loss decreasing as the load increases.

The only care required in operating this meter is in placing the sensitized paper in the holder. In order to do this satisfactorily, a dark room should be built in a convenient portion of the station ; a window of dark yellow glass in this room will provide plenty of light to the operator, but if more light is required, this window can be covered with yellow post-office paper and an incandescent lamp suspended before it. The sensitized paper in rolls of sufficient length for one month's use comes in sealed packages and must only be opened and placed in the holder in the dark room. A boy can be instructed to collect the boxes, as skill is not required. As stated before, the meter number is printed on the diagram every hour; therefore it is not necessary to keep any record of the box itself.

It is evident that a meter which provides means to compute the current consumed in a detailed manner has advantages which other meters do not possess, inasmuch as any question as to the correctness of bills rendered can be satisfactorily explained by referring to the diagram or chart made by the meter which is in dispute.

The patent office reports show numerous devices for securing the record of the ammeter needle on a moving strip of paper by the use of a syphon pen or pencil. In all such cases, however, the element of friction is so apparent as to make their use prohibitive.

---

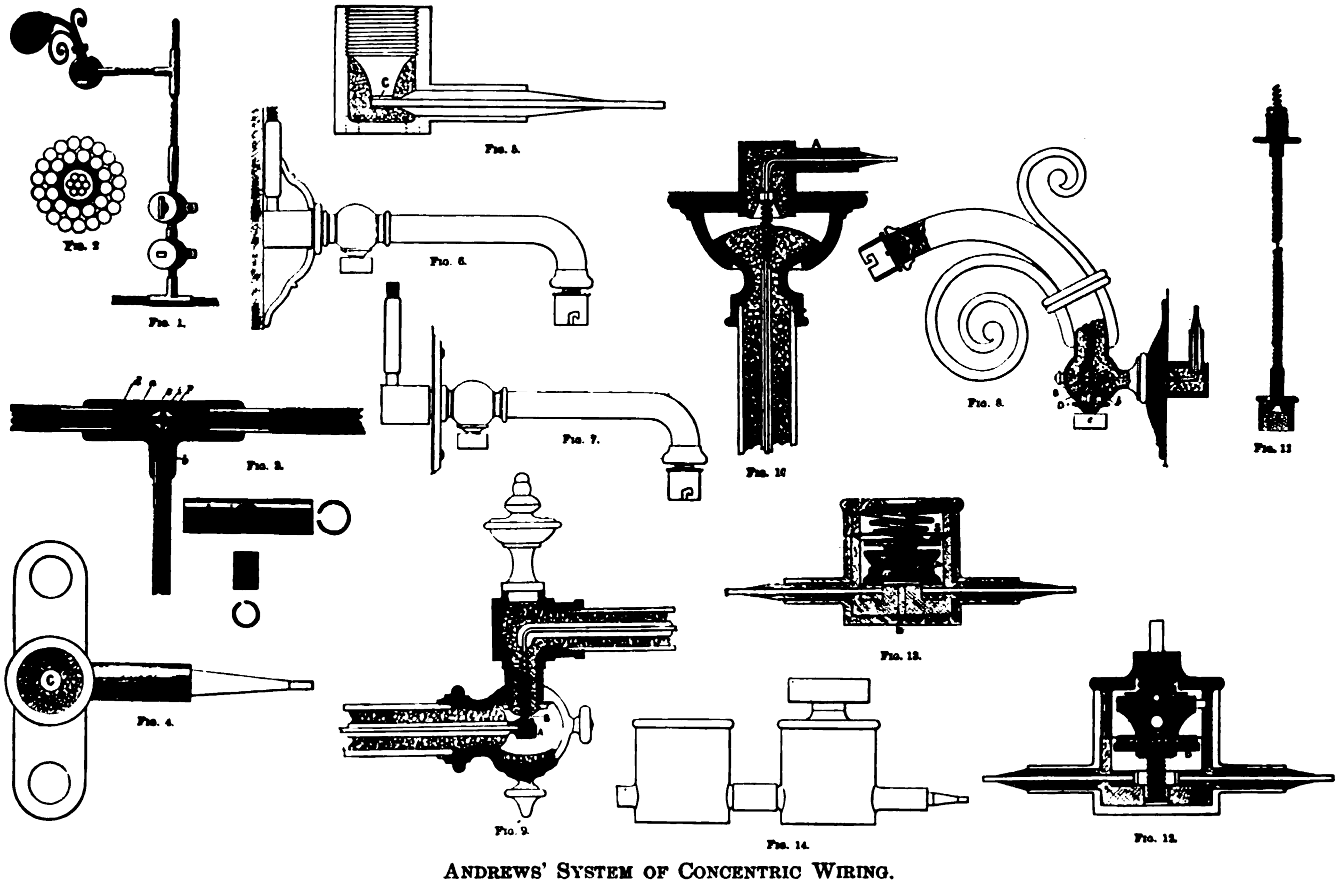
[1] Abstract of a paper read at the General Meeting of the American Institute of Electrical Engineers, May 21, 1891.

ANDREWS' SYSTEM OF CONCENTRIC WIRING.[1]

THE system of concentric wiring shown in the accompanying illustrations, is not only the result of recent thought and experiment, but has been perfected during several years of gradual development. An idea of the general appearance of the wiring is given in Fig. 1, from which it will be seen that the system resembles more that of gas than what we are accustomed to in the present electric wiring, and it possesses to a marked degree the substantial and simple character in all details that we find in the gas-pipe system, besides having a completely systematic and interchangeable arrangement of all parts. One of the great advantages gained by the system is safety against fire and interruption. This result is gained by the construction of the wire or cable in which the one wire, say, the lead, is completely surrounded by the other, with a waterproof durable insulation between them, and the surrounding conductor is made very heavy as compared with the central, for the purpose of supplying ample metal to secure an absolute short circuit in the case of any fault happening which would generate heat and break down the insulation. The class of wire most employed is copper, with vulcanized india-rubber insulation, armored with galvanized iron wires which form the surrounding conductor. The cross-sectional area of the armoring is usually made seven times that of the central conductor, to maintain the same resistance in both. When the cables are larger, the armoring or outer conductor has to be laid on in two layers, as in Fig. 2, in order to secure sufficient sectional area without increasing the diameter excessively. The smaller size wires, when they are to be laid on the face of the walls, are reduced in diameter to ¼ inch by using copper outer conductors as well as inner, but this is only recommended when the wires are exposed to view. When the wires are to be laid in plaster, they are covered over the outer conductor with a bituminous compound and yarn for protection against possible acids. Beyond this, no protection is used or required. An idea of the exceeding neatness of this mode of wiring may be gathered from the fact that the diameter of a wire to carry five lights is only $\frac{5}{16}$ inch, which takes the place of a wood casing measuring 1½ inches by ½ inch. Larger cables are even smaller in proportion.

The jointing of two lengths of wire together, or of a branch to a main, was a matter of considerable difficulty, which has been entirely overcome in the new joint, of which Fig. 3 represents a section. After preparing the place for the joint by cutting away the outer conductor, and tapering the insulation from both sides, so as to expose the central conductor, C, the inner conductor of the branch, *b*, previously prepared, is joined on and soldered. The insulation is then lapped on, first, a layer of pure india-rubber, P; secondly, an intermediate layer or separation, I, of india-rubber and soapstone; thirdly, a lapping of india-rubber mixed with sulphur, S. The joint thus prepared is wrapped with silesia cloth, *a*, and copper sheaths, *d*, are placed over the spaces cut in the outer conductors. An iron mold is now held round the joint by screws, and a molten metal, fusible at a low temperature, is poured in at a suitable gate; the mold when cold is removed. This method of making good the outer conductor is most effectual. The parts of the joint are completely soldered together, and the heat of the metal thoroughly vulcanizes the india-rubber of the joint. Joints such as these are not only better than the old cast iron or brass box, but they are also much cheaper. The joints, with the fittings, switches, and fuses, &c., and the wires are made in the same way, such articles being provided with a projecting tube and wire. The part of a fitting which is connected to the wiring is called a wall socket, and is illustrated in Figs. 4 and 5. It consists simply of an angle or knee provided with lugs for fixing to the wall or ceiling. A central wire, *w*, attached to a contact, C, passes out of the trunnion, T, and is cut short ready for jointing to the central wire of the leads, as previously described. The contact, C, is held firmly in position by an insulating stone, manufactured for the purpose. This socket may either be fixed to the face of the wall and covered with a hollow plate, as in Fig. 6, or it may be sunk beneath the face of the wall or ceiling with its opening flush with the face, as shown in Fig. 7. Fittings intended to screw into this socket are provided with a male screw end and a projecting spring, as shown in Fig. 8, which makes contact on the contact, C, of the wall socket. This spring is attached to the central wire of the fitting, which terminates in a recessed contact at the other or lamp end, into which may be screwed the lamp direct or a lamp holder. All parts of fittings are constructed with a male and female end, and having started with a fixed female screw in the socket, it is evident that it must always be a recessed end that is left unprotected, thus securing safety against possible short circuits by bridging the contacts at the ends. The insulation of the contacts and springs, and wherever a contact is made, is stone composition of great hardness.

The switch used in conjunction with these fittings is shown in section in Fig. 8. The central wire of the fitting is opened, and made to terminate in contacts, *a*, *a*; a brass disc, B, is placed facing these contacts, and is held from them by a spring, *c*; a cam mechanism, *d*, is provided to move the disc to and from the contacts by turning the handle, *e*; on the stem of this handle



ANDREWS' SYSTEM OF CONCENTRIC WIRING.

---

[1] London *Electrical Review.*

there is a cross-head pin, which works on the face of the cam, forcing it to, or from, the contacts according to the direction of turning. A pin, *f*, in the cam works in a wide slot in the frame, and prevents the cam turning beyond the limits of the slot; having a certain latitude in the slot, the cam flies back quickly when the handle is turned towards the off position, thus securing a sharp break of the circuit. The insulation of this switch is throughout the same stone composition as is used at the contacts of the fittings.

Thoroughly practical jointed fittings are exceedingly easily made in this system, as will be understood from Fig. 9. In outer appearance the joint resembles a gas joint. The central wire of one part of this joint terminates in a cup contact, *a*, in which presses a spring, *b*, attached to the contact wire of the other part of the fitting.

Ball and socket joints are of equal simplicity, as will be seen from Fig. 10. A is the usual wall socket, with its recessed contact, B, upon which presses the terminal spring of the central wire. The fitting is hung on a ball joint, C, the centre of oscillation of which is at the contact, B.

Raising and lowering pendants are constructed with two telescopic tubes, insulated from each other with Andrews' patent stone insulation previously referred to. Flexible pendants are also used with this concentric system, and the flexible wire being concentric, has an even, round appearance. These pendants are usually provided with a union junction to screw into the roof or wall socket, as shown in Fig. 11.

The larger switches for operating a number of lights are of similar construction to the one shown in Fig. 8, for a single light; the difference being that the contact disc is made to rotate with the handle spindle, by passing a square prolongation of the latter through a square hole in the disc, *d*, fitted with insulation as shown in Fig. 12. By giving rotation to the contact disc in this manner, a rubbing contact is secured.

The fuse of this system looks like a switch without the handle. It is a brass box, Fig. 13, which forms the outer conductor containing a plug, P, upon which is mounted a tin fuse wire, *w*, attached to contacts fitted diametrically opposite. These contacts, when the plug is in position, meet the contacts of the ends of the central conductors that pass out of the box for connecting to the leading wires. A spring, S, in the cover gives pressure at the contacts. The plug is prevented from turning by a fixed pin, *a*, passing through it to one side of the centre.

Switches and fuses are united together as shown in Fig. 14, for the purpose of making a neater arrangement. The method of making this junction is as follows: The conductors from the contacts of the switch and fuse are tubes concentric with the trunnions of the switch fuse with which they terminate flush. These tubes are connected together by fitting a bundle of hard copper wires tightly into them, and then drawing them together by means of the screw-sleeve on their outer trunnions. This is found to make an excellent connection.

The arrangements of circuits adopted in practice with this system is a facsimile of that employed with gas, the distributing box system, with double wiring, not being found necessary, as the safe nature of the system does not require the introduction of so many fuses. The usual number of amperes to a fuse is 8, or one fuse to every, say, 12 lights, and with a view to securing absolute safety in the event of a short circuit, the smallest wire used is No. 15, S. W. G., it being considered that this size could carry 12 amperes without becoming overheated.

Appointments, Etc.

MR. F. G. STONE is now the superintendent of the Aluminum Brass & Bronze Co., at the Bridgeport factory.

MANAGER B. B. NOSTRAND, JR., of the Sing Sing, N. Y., Electric Lighting Company, has accepted a similar position with the Peekskill Electric Light and Power Company, and will, in future, look after the interests of both companies.

ELECTRICIAN HINCKLEY, of the Citizens' street railway, Indianapolis, Ind., has resigned because Mr. Shaffer was forced out of the presidency. The company has chosen as his successor Maj. Jewall, who put in the Kansas City line. Mr. Jewall has been in the city looking at the proposed new Irvington line, and has gone to Pittsburgh to examine some ideal electrical work there. The Irvington line is to receive his first attention upon his return.

ELECTRICAL CRANES FOR SOUTHAMPTON.

The harbor authorities of Southampton, England, the great mail port, have decided to adopt electrical cranes for the unloading of vessels, on account of the greater rapidity with which they will enable work to be performed.

Reports of Companies.

FORT WAYNE ELECTRIC CO.

The net earnings of the Fort Wayne Electric Company for the past six months have amounted to $215,000, or $95,000 over and above the amount required for the semi-annual dividend. This is equivalent to more than 5 per cent. on the total capital of $4,000,000. The previous six months yielded $161.206, or about 4 per cent., so that the entire income for the year has been something over 9 per cent., of which 6 per cent has been paid out in dividends.

College Notes.

PURDUE UNIVERSITY.

The engine and dynamo room of the electrical laboratory of Purdue University now contain a 22 h. p. Straight Line engine, a Brush and a Thomson-Houston arc, and an Edison incandescent dynamo, and a Sprague and a Baxter motor. There is also a Slattery alternating dynamo with a bank of converters for the study of alternating currents. The dynamos, as well as a Julien storage battery plant, are connected with a convenient switchboard, so that measurement work may be carried on in any part of the building. A Brackett cradle dynamometer is used in testing efficiency. The construction of a dynamo, wound compound, series, and shunt, for experimental study, has been begun.

THOMSON-HOUSTON WORK IN FRANCE.

The lighting of St. Briené, France, by the Thomson-Houston Company excites considerable interest among technical men, says our London correspondent. This company has hitherto had in France only installations for direct current; now it has completed its first installation with alternating current and transformers. A waterfall at Pont Neuf, twelve kilometres distant, is utilized. Among other peculiarities, is the coupling in parallel of alternators by means of a choking coil, and the compounding of the alternators, in order to maintain constant difference of potential at the end of the feeders, notwithstanding a fall of potential of 20 per cent. when the alternators furnish the maximum current of 35 amperes each.

PITTSBURGH.

Westinghouse El. & Mfg. Co	13¼

THE WESTINGHOUSE MULTIPOLAR RAILWAY GENERATORS.

The demand for large, slow-running generators for street railway work is constantly increasing as their advantages become more generally known and appreciated. To meet this demand, the Westinghouse Electric & Manufacturing Company is now building a compound-wound, multipolar generator, which at present is built in three sizes, namely, 125, 250, and 500 h. p.

As will be seen in the accompanying engravings, these generators resemble in general design the well-known Westinghouse alternating current dynamos. There is the same cylindrical yoke parting along a horizontal plane through the shaft, and the same arrangement of inwardly pointing pole pieces, but with a much smaller number of the latter.

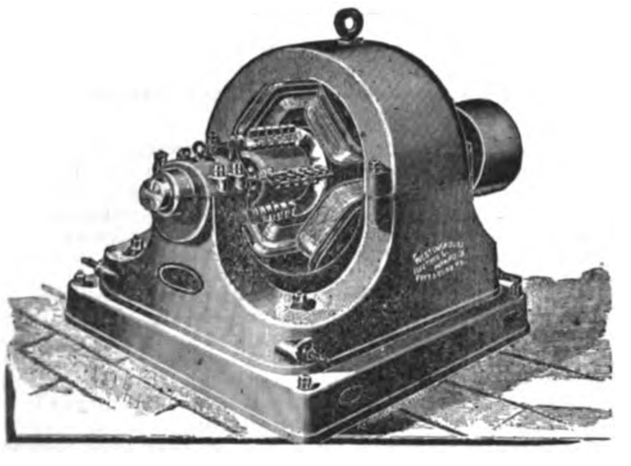

FIG. 1.—NEW WESTINGHOUSE 4-POLE RAILWAY GENERATOR.

The 125 and 250 h. p. machines have, as shown in Fig. 1, four pole pieces, and in the 500 h. p. size, Fig. 2, there are six poles. In this latter machine the shaft has a bearing outside of the pulley, which relieves it in a large degree of the bending strain, and adds much to the rigidity of the armature.

The pole pieces are built up of thin sheet-iron plates bolted together and cast into the cylindrical yoke. The shunt and series coils are wound side by side upon metal bobbins, which are then slipped over the pole pieces and held in place by bolts. The insulation of these coils, as well as that of the armature, is of ample thickness and of superior quality.

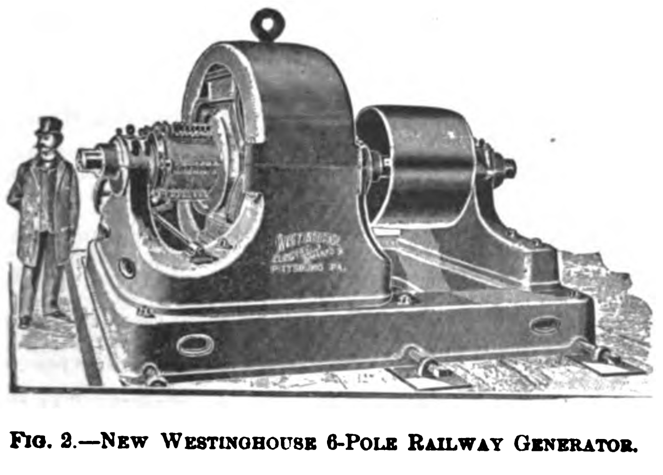

FIG. 2.—NEW WESTINGHOUSE 6-POLE RAILWAY GENERATOR.

The bearings are self-oiling as well as self-aligning, and a large amount of bearing surface is obtained owing to the length and large diameter of the journals.

The armature is of the Gramme ring type, the core being laminated in the usual manner. The armature and series coils are wound with wire of large capacity, and, as a consequence, the heating effect is almost unnoticeable, and the electrical efficiency of these generators is claimed to be from 94 to 96 per cent. at full load. These generators are wound for 500 volts, but they can be worked up to 550 or even 600 volts with the same armature speed, by throwing resistance out of the shunt circuit by means of the hand regulator.

The excellent design of these generators is probably most apparent in the matter of regulation. The action of the series coils is such as to cause a considerable rise in voltage, as the current being drawn from the machine increases. It is claimed that even at full load this rise in voltage is sufficient to make up for any ordinary loss or "drop" in the line.

The number of sets of brushes corresponds to the number of pole-pieces, and the alternate ones, being of the same polarity, are connected together. Each individual brush has its own spring by means of which its pressure on the commutator may be adjusted, and any one of them may be removed without disturbing the others. The dynamos may be run in either direction.

We also give a view of a railway switch-board, Fig. 3, equipped with Westinghouse appliances, some of which, such as the circuit breaker and lightning arrester, have already been described in detail in these columns. This board accommodates three generators and three feeders.

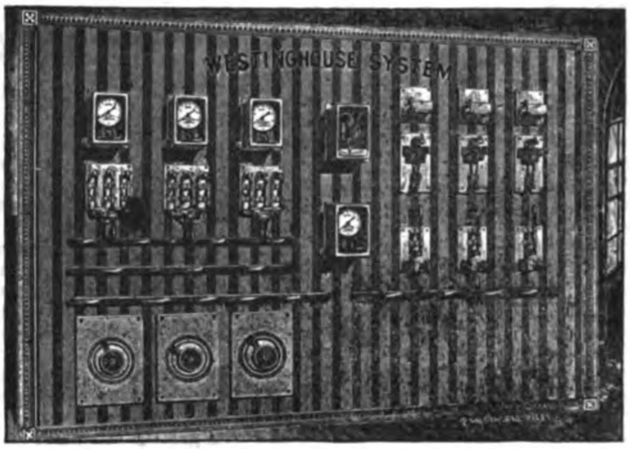

FIG. 3.—WESTINGHOUSE RAILWAY SWITCHBOARD.

ARC LAMPS AND LARGE INCANDESCENTS.

At a meeting of the South Wales Institute of Engineers, writes our London correspondent, Mr. Polybank gave some interesting particulars of his experience with arc lamps and with large incandescent lamps of the Sunbeam type, at Swansea Docks. He had found that a 2,000 candle-power 10 ampere arc lamp, with two 11 mm. carbons 11 in. long, would burn only 12 hours with proper current. The cost of such a lamp, taking 10 amperes at 50 volts, and working from sunset to sunrise throughout the year, or about 4,874 hours, was £15 18 7. The globes surrounding the carbons cost 10s. to 12s. each, and sometimes broke, but no allowance had been made for this. Comparing such a lamp with a 500 candle-power Sunbeam lamp, the workmen very much preferred to work with the latter, as it gave a steadier light and was not so trying to the eyes. The average length of life of these lamps was about 1,500 hours, though some had broken down after only 400 hours' work. The total cost of working was £11 19 0. The lamps, when first put up, took 10 amperes at 100 volts, but after the lapse of from 800 to 1,000 hours the current was reduced to 8.5 amperes. The bulbs blackened somewhat, but not so seriously as might be imagined, as some lamps which had been burning over 2,000 hours still gave a fairly good light, which proved satisfactory to the workmen.

THE TROLLEY SYSTEM IN CLEVELAND.

Taking up and answering some criticisms of the Providence *Telegram* on the trolley system, the *Cleveland Plain Dealer* says: "The trolley system has been the greatest boon to Cleveland. It has developed suburbs, made possible the building of the thousands of small homes east, south and west and been a great factor in the 10,000 a year increase of population during the last decade. It is by no means a perfect system, but it is the best that inventive genius affords to-day. A few citizens of Providence should come out of their dens and see the world. Let them come to Cleveland and we will show them what a live city is and what an efficient street railway looks like."

Letters to the Editor.

Notice to Correspondents.

The Editor respectfully requests that all communications may be drawn up as briefly and as much to the point as possible.
order to facilitate reference, correspondents, when referring to any letter previously inserted, will oblige by mentioning the page on which it appears.
Sketches and drawings for illustrations should be on separate pieces of paper.
All communications should be addressed EDITOR OF THE ELECTRICAL ENGINEER *150 Broadway, New York city.*

THE REFLECTING GALVANOMETER: YOUR ABUSE OF IT AND ITS USE TO YOU.

When I come to reflect, I think I can spot the author of an article, which appeared in one of your contemporaries recently, entitled "Abusing the Galvanometer." But luckily, hard words break no bones, and, although I confess to being a "dead beat," shining by borrowed light, still the scale of his abuse compels me to offer some resistance to the charges he has made against me. I will try to negative the assertions current throughout his positively unmerited abuse, and strive to clear myself of the constant errors he so dogmatically attributes to me. Had he used a well-designed and scientifically constructed galvanometer he would have written otherwise, and herein is to be found the key of his tone.

I admit that there are some disreputable gals. whose sole value lies in the amount of polished brass, glass and lacquer they possess. If he has been using one of these highly finished nondescripts with unsteady base, the centre of gravity of whose astatic system is badly positioned on a long suspension, with soft watch spring magnets, the force of which is, on the slightest pretext, ready to become reversed or weakened, then I will allow that the unjustifiable bad temper of the steel will justify a worse one in the electrician.

But what are his worries and troubles compared with those of a really good gal. in the hands of a bad electrician?

Just a word from my side of the question, if you please! I have been sworn at until I trembled in every fibre because my shunt has been left open, and a current from 500 cells has therefore literally "knocked spots out of me," and so thoroughly upset me that I didn't know which way to turn!! Then when the brainless individual discovered his blunder he has petted and patted me, and tried his vapid best to bring me round, and, not succeeding, has shaken me like a dice box!! Finally he has given me up in despair, and then I, always anxious to do my best, according to the power given me, have, when left alone come round gradually of my own volition.

He has used the most frightful language to me because he could not find the spot. He has taken me off my stand, opened me and ruined my fibre, to find out why I would not indicate, and replaced me with a bang and another explosion of temper, which lasted until his "grey matter" became active enough to show him that my lamp had gone out or perhaps had never been lit! He has sent currents of from one to 1,000 volts through me until my mirror has become statically rigid, and then, what wonder if I do "kick" at times and fly off the scale?

It is hard to have a fellow stamping like a mad bull because he gets no sign of life from me until he remembers he has left out the battery plug!! If, also, he will insist on putting down the wrong key, what can I do but keep quiet? And what can a sensitive, delicate gal. do to quell an atmosphere of sulphurous invocations and anathemas, proceeding from an ovoid brained fellow who hasn't sense enough to find out that I am disconnected somewhere, who is too dense to be able to distinguish between an intermittent and a permanent disconnection; and who, when things come right by accident, is stupid enough to be content and trust that things will keep right, until he bursts forth in another rage because, at a most particular moment, I can't help going wrong?

How can I be expected to give reliable results when placed on a foundation of eggshells, fish bones and old tomato cans, and am bombarded on all sides by flying machinery, and demoralizing inducements to go wrong, from pigs of iron whose position and duty is to elevate even an elevator? If I am placed in a position where temperature ranges from boiling to freezing point, am I to blame because, when shrivelled and contracted, or relaxed and languid, I cannot always give the same result?

No, Sir. When things are so bad as the writer in your contemporary would have us believe, it is either that he does not know his work, or that his galvanometer is but a sham and shoddy imitation. Possibly it may be both causes together! In the hands of a competent man I am undeniably, although perhaps a little touchy and supersensitive at times, the most delicate and absolutely reliable instrument of physical research on earth. And the man who, from ignorance or choice, "imperils his hereafter," by the use of a worthless gal., deserves to go where Charity teaches us to hope Lady Macbeth is not. If he is *compelled* to use it, then his redemption has been wrought down here; he has earned the indulgence of St. Peter for all sins short of murder, and the old Saint would probably look even on that as a virtue if the victims were the makers or the owners of the instrument, and would at once admit him to those regions of bliss where cables are unknown and the weary electrical engineer knows no drop of potential!!!

A.

European Correspondence.

LONDON.

Royal Society's Conversazione.—Electric Light Litigation.—Electric Light in the City.

THE annual conversazione of the Royal Society was held last week, at Burlington House. Sir Wm. Thomson, the president, received the numerous guests. The new Wimshurst electrical machine was exhibited, but in this case the essential parts of machine consisted of one rotating disc and four inductor plates, each having its own brush, and convertible into a machine capable of supplying a large and constant electric flow.

Professor Oliver Lodge showed a rotating mirror driven at a high speed, designed for analyzing the electric spark, and for observing the speed of electric pulses along conductors of various kinds. He had also a pair of resonant Leyden jar circuits. One circuit was fed from a Wimshurst machine and when sparking took place a similar effect was produced in the other circuit which was several feet away and quite isolated from the first circuit. Mr. W. Crookes exhibited his set of tubes for exhibiting phosphorescence in high vacua, and which formed the subject of the inaugural address to the Institution of Electrical Engineers. Mr. Shelford Bidwell demonstrated the action of light in modifying the electrical resistance of selenium. An electric lamp was lighted, a bell rung, and other effects produced by merely shading the beam from a lamp. This beam was directed on to a selenium cell made of two fine copper wires wound very close together on a slip of mica one side of which was coated with a thin film of selenium. A current flowed through the coils of a relay, and was greater when the light fell on the cell than when it was shaded. The alteration in the resistance of the selenium brought about the action of the relay, and the main current was turned on or shut off as the case might be.

An electric supply company in London has been summoned under the Act for refusing to supply a customer during the daytime with the electric light. The case when brought before the courts should present some peculiar points in electric light legislation.

Electric lighting in the city is pushing on. The central station at Meredith's Wharf, Bankside, is nearly ready to receive the machinery. Mains have been laid in Queen Victoria street, and the iron standards erected. It is said that the first lighting will take place next month.

H. S.

LONDON, May 13, 1891.

Electric Launches.—Reduction in Telegraph Rates.—Ship Wiring.

ORDERS for electric launches are being sent to the London firms in profusion. Among them may be mentioned a boat 40 feet long for the Russian Government, to be built by the General Electric Traction Company.

It is anticipated that the recent reductions in Australian telegraph rates will cause an extraordinary influx of telegrams; to meet the expected demand the cable companies have prepared by laying new cables.

It is stated that the contract for the electric cars at Barking Road has been renewed with the General Electric Traction Company at an increase of 1*d* per mile, which brings the price per car mile to 5½*d*.

In his lecture on "Electric and Magnetic Screening" at the Royal Institution, Sir Wm. Thomson condemned the use of the "single wire" system of lighting ships by electricity, on the ground that observation has shown it to produce an error in the ship's compass of 3 degrees to 7 degrees, in spite of every care being taken. It has been argued that the iron hull which completes the circuit in the single wire protects the compass from the deflecting influence of the current, but Sir William declared that this argument was fallacious. In order to do so with any degree of success, the hull and decks of the ship would have to be several feet thick of iron. Even in the conning tower of Her Majesty's ship *Orlando*, which is belted with iron one foot thick, the terrestrial magnetic force on the compass is only reduced to one-fifth of what it is outside.

LONDON, May 2, 1891.

Legal Notes.

THE EDISON LAMP LITIGATION.

The suit of the Edison Company against the United States Electric Lighting Co. for alleged infringement of the Edison electric lamp patent, usually known as the carbon filament patent, which came up for hearing in the United States Court before Judge Wallace in this city on May 25, is perhaps the most important, in view of its relations to the entire industry of incandescent lighting, of any of the various suits now pending between the principal electrical interests. It was commenced as long ago as 1885; eminent counsel have been employed on both sides, and a vast amount of evidence, filling half a dozen large printed volumes, has been taken. The issues are substantially the same in this case as in those already tried in England, and in which the Edison patent, after some vicissitudes, was ultimately sustained. The differences, not only in the law, but in the state of facts as presented by the evidence, from those in the English cases, render it rather difficult, however, to predict the ultimate result.

The case was opened on Tuesday by Mr. Richard N. Dyer, who spoke for two days in behalf of the Edison Company. His argument was that the invention of Edison was the foundation of the modern incandescent lighting system; that it consisted in placing a carbon filament of high resistance and small radiating surface in an exhausted glass globe. He reviewed the state of the art at great length, and claimed that prior to the date of Edison's discoveries, inventors had been following the wrong track. His presentation of his facts was admirable, and was heard with great interest. The case for the defence was opened on Thusday by Gen. S. A. Duncan. The argument of Gen. Duncan was acknowleded by all to be a most masterly effort; his points were presented with great skill, and ably supported by an array of facts, in which no feature, however small, appeared to have been overlooked. He contended that Edison's invention, in view of the condition of the art, showed little that was new; and even admitting the importance of the features of the high resistance and small radiating surface, in an incandescent burner inclosed in a vacuum, that these then were all found in a prior application made by Edison himself. He adverted to certain papers in the Patent office which, he alleged, showed that the Edison Company itself did not regard the patent in suit as covering the invention which it is now sought to embrace within it.

The arguments are in progress as we go to press.

Obituary.

DAVID BROOKS.

The death of the veteran electrician, David Brooks, occurred at Philadelphia, on May 30. He was born at Brooksvale, near Cheshire, Conn., on January 26, 1820. He left college at the age of twenty years, and took a place as instructor in mathematics in the United States Navy. At this time Professor Morse and his associates were engaged in their first experiments with the electric telegraph. Mr. Brooks left the Navy in 1845, to devote himself to the development of this great invention. During that year he put in operation, in connection with James D. Reid, the first telegraph line built in America after Professor Morse's experimental line between Baltimore and Washington. This ran from Lancaster to Harrisburg, Penn., and Mr. Brooks received the first message sent over it. In the following year he built the line across the Alleghanies, connecting Philadelphia and Pittsburgh.

From 1854 to 1867, David Brooks was in the service of the old Atlantic and Ohio and the Western Union companies. In the latter year he resigned, and devoted himself to his many inventions and improvements in telegraph and telephone service. In 1873 he was appointed by General Grant United States Commissioner to the Vienna Exposition. Mr. Brooks' inventions have been of great importance in the development of telegraphy. The deceased was a vigorous writer, not slow to take his share in any controversy going. The last articles that he wrote were prepared specially for THE ELECTRICAL ENGINEER, and were published in these columns during May.

EDWARDS H. GOFF.

The death is announced of Edwards H. Goff in this city. Mr. Goff was at one time quite active and prominent in electrical matters on account of his association with Thomson-Houston interests in New England and afterwards through his presidency of the American Co., which owned the Fuller-Wood system. After the collapse of his electrical enterprises, he became interested in the *Daily Graphic*, and at the time of his death was engaged promoting the American Export and Trading Co., a concern whose business it was to develop and control trade with South American countries. Mr. Goff was a man whose readiness to lend his name and wonderful energy to all manner of visionary and doubtful enterprises led him into many troubles and disasters, in which others often became seriously involved. It deserves mention that he presented a complete electric lighting plant to the Government to be used for the Bartholdi Statue of Liberty, in New York Harbor.

Society and Club Notes.

HIRAM S. MAXIM BEFORE THE NEW YORK ELECTRIC CLUB.

"The Tools of Modern Warfare" was the subject of a lecture delivered last Thursday night before the Electric Club by Hiram Maxim, the well-known electrical pioneer, and the inventor of the Maxim gun. Mr. Maxim first briefly described the old brown and black gunpowders, and then followed with a description of the smokeless powders just coming into general use. Samples of each powder were fired. Next he showed the evolution of the modern rifle, beginning with the flint lock of the Revolutionary period, and continuing through the old percussion lock, the Springfield rifle, which had to be cocked by hand every time it was fired; the Remington, the Peabody or Martini-Henry, the Lee, the Winchester, the Colt, the Mannlicher, and the Birdson.

Mr. Maxim's description of his own arm, the Maxim, was illustrated by one of the guns, which was mounted in the parlor. A tube was arranged so as to carry the gases up the chimney, and at a signal forty-nine shots were rattled off more rapidly than they could be counted or timed. Two shots were fired so rapidly that but a single report was heard. Then the inventor played "Tom, Tom, the Piper's Son," each note being sounded by a shot from the gun. This was done to show that the gun can be fired as regularly or as irregularly as desired. From a forty-pound gun of this type 1,001 shots have been fired in one and a half minutes. It is now used in nearly all the armies of Europe.

The lecture was intensely interesting, and aroused so much discussion and talk that time did not admit of any description by Mr. Maxim of his experimental work in aerial navigation as carried on by him in England, where he is now residing. Among the participants in the discussion was Dr. Gatling, the inventor of the Gatling gun.

After the lecture, Mr. Maxim held a kind of informal reception, and renewed acquaintance with many of his old friends in the electrical field.

The next meeting of the Club will be held some time in June—probably the third Thursday—and will take the shape of a smoking concert, being the first effort of the Club in this direction. It is proposed not to go outside electrical circles for talent, and the Entertainment Committee have been agreeably surprised to find an abundance of musical skill at their disposal. The programme will also be reinforced with some electro-harmonic novelties, of which due notice will be given.

At the last meeting of the Club Board, thirty-one active and associate members were admitted. These added to the round score admitted in April, and the 42 now applying, show a gain of nearly 100 members within three months—a big step forward that must be very gratifying to Presidents Madden and Insull and those who have been co-operating with them to put the Club on the right basis.

FRANKLIN EXPERIMENTAL CLUB, NEWARK.

At the last regular meeting of the Franklin Experimental Club, May 19, 1891, Prof. Geo. C. Sonn delivered an intensely interesting and instructive lecture on "Seismology," or phenomena of earthquake disturbances and methods of studying the same. Prof. Sonn dwelt upon the various theories prevalent, upon the subject of earthquakes, tidal waves, etc., and explained the methods adopted from the earliest times to the present day in the study and recording of the various disturbances going on in various parts of the earth's structure. The lecture was illustrated by magic lantern views of the most important earthquakes and their effects in Japan, Java, Sandwich Islands, Lisbon, Charleston, and elsewhere, and also by diagrams, prepared by Prof. Sonn, of the electrical and other methods employed in recording the time and duration of the disturbances, and the number and general character of the movements.

Some interesting pictures were shown of various buildings and the effects of the shocks upon structures placed in certain positions, and he explained that as nearly all of the impulses moved in one direction, it was customary in earthquake countries to pass strong laws stating how buildings were to be set, whether windows and doors, etc., would be allowed in walls which ran in certain directions, relative to the seismic movements, the character and material employed. The President exhibited some interesting samples of lava, and earthquake souvenirs, collected by him at Herculaneum, Pompeii, and the Island of Iskia. Prof. Sonn sails for Europe shortly, and during his visit abroad will visit the Electrical Exhibition in Frankfort, and will prepare an interesting report for the Franklin Experimental Club.

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED MAY 26, 1891.

Alarms and Signals :—

Police Signaling Apparatus, H. A. Chase, 452,771. Filed July 18, 1890.
Includes a special form of ground-detector, located at central station; also a special construction of signal transmitters.

Electro-Mechanical Gong, F. W. Cole, 452,981. Filed Dec. 9, 1890.
A quick-acting gong.

Electro-Mechanical Gong, F. W. Cole, 452,982. Filed Dec. 9, 1890.
Details of construction and operation. A part of the releasing mechanism serves as a retractor for the armature of the electro-magnet.

Clocks :—

Electric Transmitting Clock, H. S. Prentiss, 452,955. Filed June 6, 1890.
Relates to electro-mechanical clocks, and especially to the connections of the primary clock with the transmitter.

Synchronizer for Electric Clocks, H. S. Prentiss, 452,956. Filed June 6, 1890.
A switch actuated at determined intervals breaks contact at the main line and closes it through a synchronizing line.

Dynamos and Motors :—

Electric Motor, C. J. Kintner, 452,795. Filed June 14, 1890.
A motor designed especially for use with revolving fans.
The field-magnet core is divided at its neutral point. The vertical armature shaft has a longitudinal movement in its journal bearings; the fan is attached to the lower end of the armature shaft.

Electric Motor or Generator, W. K. Freeman, 452,984. Filed Jan. 13, 1891.
Relates particularly to the form and construction of the frame and field magnets.

Electric Motor or Generator, W. K. Freeman, 452,985. Filed Jan. 13, 1891.
Relates to frame and field magnets, their form and construction.

Electric Switch, W. K. Freeman, 452,987. Filed Jan. 15, 1891.
A rheostatic switch for the control and regulation of motors.

Armature for Dynamo-Electric Machines or Motors, E. Thomson, 452,951. Filed March 5, 1890.
A construction for ring armatures designed to facilitate the winding and replacing of the armature coils.

Electric Motor, E. Baker, 453,081. Filed July 5, 1890.
Designed to run upon an elevated track for carrying small parcels. Has its armature inclosed within the driving wheel and its field magnet suspended beneath the track.

Automatic Electric Switch Mechanism, H. H. Blades, 453,082. Filed Sept. 19, 1890.
An automatic rheostatic switch for controlling and regulating the introduction of current to electric motors.

Lamps and Appurtenances :—

Incandescent Electric Lamp, I. J. Flagg, 452,780. Filed Sept. 17, 1890.
Relates to water and moisture-proof insulating material within the socket.

Hanger for Incandescent Lamps, J. A. Matteson, 452,799. Filed Dec. 24, 1890.

Adjuster for Electric Lamp Reflectors, J. E. Hamilton, 453,008. Filed Jan. 3, 1891.

Electric Display Burner for Oil-Lamps, W. A. Drysdale, 453 041. Filed Feb. 16, 1891.

Device for securing an incandescent electric lamp upon an ordinary form of oil lamp.

Measurement :—

Electric Meter, W. K. Freeman, 452,986. Filed Jan. 13, 1891.

An electric motor meter. As the increase in the rate of revolution of the armature is not directly proportional to the increase of current the mechanism connecting the motor with the registering dials includes a revolving member circular in cross section but with a longitudinal contour corresponding to the characteristic curve of the motor. The motor shaft and the shaft carrying the curved members are in a vertical position and the latter carries at one end a fan propeller revolving in a homogeneous liquid; it has freedom of movement longitudinally and is raised or lowered through the action of the fan propeller. The movement of the registering apparatus is controlled by the position, higher or lower, of the shaft carrying the curved member.

Metal Working :—

Art of Repairing Metal Structures by the Aid of Electricity, E. E. Ries, 453,164. Filed Nov. 9, 1889.
Employs the process set forth in the same inventor's patent of Sept. 20, 1887, No. 370,282. The present invention consists in cutting out a defective portion or section of a metallic structure, inserting a new portion or section and electrically welding at the ends or edges.

Miscellaneous :—

Hollow Braided Lightning Rod, G. R. Kress, 452,796. Filed Nov. 8, 1890.

Multiple Fuse Block, L. B. Favor, 452,875. Filed Nov. 3, 1890.
Improvement upon the construction shown in the same inventor's patent of July 1, 1890, No. 431,186.

Grounding Device for Lightning-rods, C. M. Radford, 452,983. Filed Jan. 19, 1891.
A terminal adapted to be readily driven into the ground.

Multiple Cut-Out for Electric Distribution Systems, E. P. Warner, 453,089. Filed Feb. 6, 1891.
Applicable to multiple-arc distribution. Designed to reduce the number of manipulations required.

Adjustable Support for Electric Wires, T. H. Brady, 453,036. Filed Feb. 18, 1801.
A bracket adapted for use as a right or left-hand bracket or as a hanging or standing bracket; avoids the necessity of special brackets for different uses.

Electrical Safety Switch, G. L. Hall, 453,046. Filed Mar. 19, 1890.
Designed to open a line at one or more points upon a failure of the current.

Electric Fuse Box, W. Edson, 453,111. Filed Jan. 21, 1891.
A multiple fuse-box. If a fuse burn out another may be substituted by a simple movement.

Railways and Appliances :—

Automatic Safety Electric System for Locomotives, E. Deming, 452,871. Filed Sept. 18, 1890.
Electro-mechanical devices for automatically applying the brakes of a railway train, and simultaneously closing the throttle valve of the locomotive.

Automatic Safety Electric System for Railways, E. Deming, 452,872. Filed Sept. 20, 1890.
An electro-mechanical system for stopping automatically one or more trains when dangerously near each other, and to do so independently of the engineer.

Automatic Electric Safety System for Railway-Switches and Draw-bridges, E. Deming, 452,873. Filed Sept. 22, 1890.
An electro-mechanical system for stopping a train automatically when within a predetermined distance of an open draw-bridge or an open switch.

Automatic Electric Safety System for Railway-Crossings, E. Deming, 452,874. Filed Sept. 24, 1890.
For automatically stopping a train within a predetermined distance of a crossing when another train is at, or near, the crossing on another track.

Electric Railway, R. M. Hunter, 452,980. Filed Apr. 28, 1888.
Includes two or more electric motors upon a car, reversible commutator brushes for each motor, means controlled by the operator for actuating the brushes to reverse the motor, resistances in the motor circuit and automatic control of such resistances.

Air Brake System, W. W. Slater, 452,942. Filed Mar. 19, 1890.
An elecro-magnetic system for controlling air-brakes.

Electric Motor for Wheeled Vehicles, R. S. Dobbie, 432,992. Filed May 9, 1890.
An electric motor elastically supported, has its rotary part secured to a sleeve which surrounds an axle of the vehicle, and is provided with elastic or yielding bearings at its opposite ends between it and the axle.

Support for Trolley Wires, G. K. Wheeler, 453,070. Filed Nov. 21, 1890.

Trolley Wheel, J. Sullivan, 453,091. Filed Feb. 19, 1891.
A special construction, adapted to break up and dislodge ice or snow accumulating upon a trolley wire.

Electric Railway Signal, W. C. Walter, deceased, S. L. Walter, executrix, 453,097. Filed Nov. 11, 1889.
A system of circuits and signals by which the engineer of a train will be notified if a switch is open or if the rails have spread or if a bridge has settled ahead of him, and by which also the engineers of two trains on the same track are placed in communication.

Insulating Clamp for Span Wires, W. E. Baker & C. H. Mackloskie, 453,100. Filed Jan. 9, 1891.

Electric Contact Brush, J. R. Branch, 453,104. Filed Oct. 28, 1890.
Designed as a substitute for trolleys upon electric railways.

Electric Locomotive or Street Car Motor, R. Eickemeyer, 453,167. Filed Oct. 28, 1890.
Application of the same inventor's peculiar motor to railway service. The armature shaft of a slow speed motor is directly connected to the driving wheels or their axle by a pitman.

Telegraphs :—

Sextuplex Telegraph, T. A. Edison, 452,913. Filed June 2, 1877.
For the simultaneous transmission of three messages in opposite directions from each end of a single line. Of the three receiving instruments at each end one responds to reversals, another responds to a current of either polarity that is above a medium strength, and the third responds only to a current of maximum strength.

Telephones and Apparatus :—

Telephone Receivers, C. T. Dickson, 452,775. Filed Aug. 14, 1890.
An addition to an ordinary telephone receiver of a flexible tube, one end of which leads from the air space in front of the diaphragm and the other is terminated with an ear-piece. The listener uses the receiver in the ordinary manner at one ear and the ear-piece at the end of the flexible tube at the other ear.

Coin-Controlled Annunciating Machine, H. M. Hamrick, 452,785. Filed Feb. 24, 1891.
A "nickel-in-the-slot" device for use at telephone pay-stations.

Electrical Switch-Board, J. B. Lyon, 452,921 Filed Jan. 19, 1891.
Relates to the weight and cord-guides employed in telephone switch-boards of the type known as the "Law system." A section of guide-tubes, consisting of a group of rubber tubes, provided with electrical contacts, is made integral by vulcanizing the entire group after assemblage.

Electric Connection for Distributing Telephone Lines, W. M. Goodrich, 453,000. Filed Feb. 7, 1889.
Relates particularly to multiple switch-board apparatus.

NEW YORK SUBWAYS.

Ex-Alderman Walton Storm, the newly appointed Commissioner, took his seat at the last meeting of the Board of Electrical Control. The engineer, Mr. Kearney, reported the completion of a number of subways. The secretary, on motion of Commissioner Hess, was instructed to inform the subway companies that work on all subways heretofore ordered must be begun before June 15 and completed by December 15. If this instruction is not obeyed, the resolution averred, the companies' bonds will be forfeited.

ELECTRIC RAILROADING IN ENGLAND.

The directors of the South Staffordshire Tramway Company, writes our London correspondent, have issued a pamphlet in which are set forth from various points of view, the advantages of electric traction over steam traction for tramway purposes. After stating that there are many considerations which make for the final and complete superseding of the latter method by the former, and that the authorities both of Glasgow and Leeds have extensive schemes in hand, the directors add that they have seriously considered the objections raised by the local authorities to the use of steam, and after carefully investigating the various other methods of traction they are prepared to recommend the shareholders to adopt the overhead system of electric traction.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

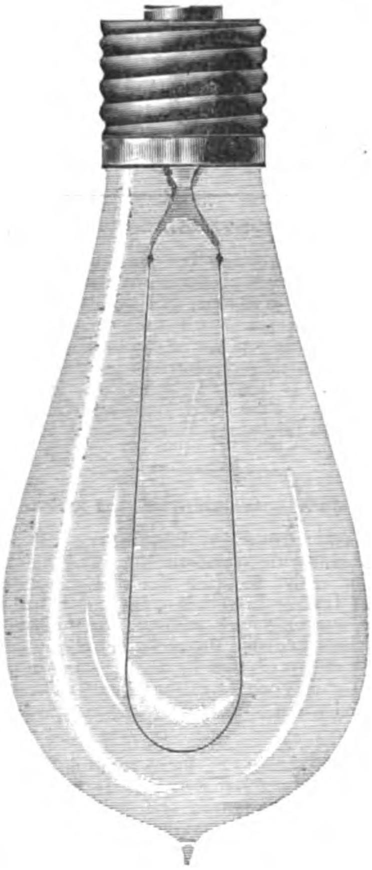
Advertise so that when a consumer wants goods in your line, he thinks at once of yours.

THE JEWELL INCANDESCENT LAMP.

We illustrate in the accompanying cut the Jewell Incandescent Lamp, for which Mr. William Hood, of Chicago, is the general agent. This lamp is the outcome of prolonged experiment, and although it has been on the market but a short time has given most remarkable and excellent results in practice.

The filament used in these lamps is remarkable for its great tensile strength and the entire absence of any discoloration due to the action of the current after it has been running for any length of time. It is made from the very best raw material and subjected to a special treatment which gives it all the properties so desirable in a reliable and efficient incandescent lamp, and it is stated that it requires less power for an equivalent amount of light than the average lamp, maintaining its normal candle power through the whole life of the lamp, which is not less than 800 hours.

The manufacture of these lamps is being carried out on an extensive scale, and the factory has been thoroughly equipped with all the new and most perfect apparatus necessary in the production of a high grade lamp; and infinite care is taken through every process of manufacture to produce a uniform and perfect product.



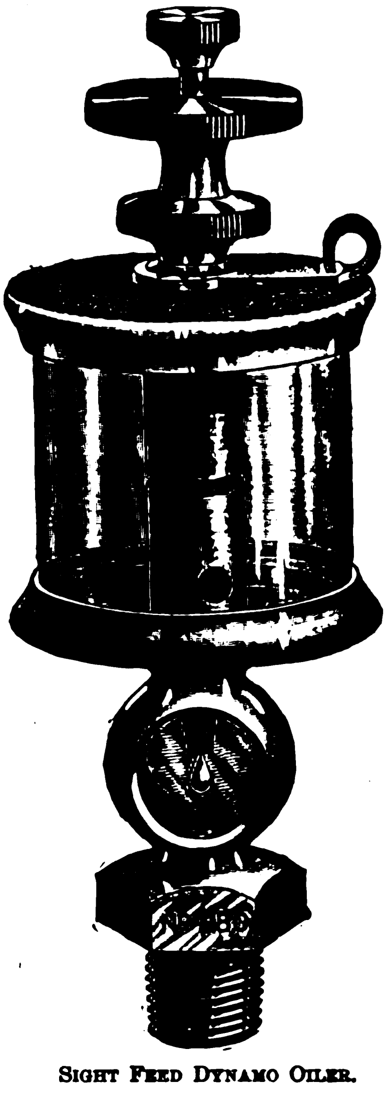
The Jewell Incandescent Lamp.

It is made with bases for all systems and of all the required voltages and of 16 or other desired candle power, and is claimed by the makers to be a thoroughly perfected, economical, and durable lamp.

Mr. H. A. Kinney, of Omaha, Neb., where he represents as general agent the Detroit Motor Co., was a caller at the Western office of The Electrical Engineer last week. He is an energetic, wide awake business man, and is finding a good field for his work in the West.

SIGHT FEED DYNAMO OILER.

The accompanying illustration shows a sight feed dynamo oiler, recently introduced by the Michigan Lubricator Co., of Detroit, Mich. It is made of heavy and finely finished bronze castings, and the regulation is effected by the main valve stem, which is secured from fluctuation by means of a jam nut.



Sight Feed Dynamo Oiler.

By operating the auxiliary or "quick-stop" valve at the top of the main valve stem, the feed can be instantly shut off or renewed to its original flow without delay. Shanks are furnished in four styles, with two holes open, two holes protected by lenses, four holes open, and four holes protected by a tube. These oilers have become very popular, both in this country and abroad.

CARHART-CLARK STANDARD CELLS.

Considerable attention has recently been given by electricians to the subject of "Standard Cells," as such an instrument is indispensable for use in calibrating voltmeters and in all cases when an absolute standard of E. M. F. is necessary. The regular Clark cell did not prove satisfactory, as it cannot be carried about and must be set up in the place where used. To overcome this serious defect, Prof. H. S. Carhart, of the University of Michigan, devoted a large amount of time to the subject, and about two years ago brought out the Carhart-Clark standard cell which has been exclusively used with most excellent results. By a special process, Prof. Carhart makes these cells so that they can be carried in the pocket or sent from place to place without any deterioration, so that they are perfectly portable. Another remarkable feature of this cell is its very low temperature coefficient, which has been reduced to .00038, this making, for all practicable purposes, the the temperature change inappreciable. Every cell is accompanied by Prof. Carhart's certificate, and they are placed on the market exclusively by Queen & Co., of Philadelphia.

A NOVEL BURGLAR ALARM SYSTEM.

Among those who have at various times turned their attention to burglar alarms is Mr. O. W. Hart, of Fall River, Mass., who has recently perfected a system of this kind, possessing a number of novel features.

In this system, after the alarm is set for the night, the person who locks up the premises presses a button on the side of the door, which, in turn, operates a drop that closes the necessary circuits for putting the alarm in working order for the night.

After this has been done, no one can enter the building, even if the wires leading to the door and window springs are in full sight. There is also a silent alarm connected to the police station, but should this circuit become broken or cut, an audible alarm on the outside of the building is instantly put in circuit; thus the building is never without protection. The audible alarm consists of a fifteen-inch mechanical gong giving 400 strokes; this gong is also an invention of Mr. Hart, and is arranged so that the alarm will ring if tampered with from the outside. All alarms are rung by an open circuit battery, and even if the closed circuit battery should "open", or become weak, the alarm will still be in operation.

Should any short circuit occur on the line, no false signal is given, but a small alarm bell is rung, giving a signal of the fact. Should this occur in the night, the main signal can be given, even with the short circuit on the line. The battery and instruments are protected and cannot be tampered with in any case.

There is a clock attached to this system which switches the current off the line at a given time and opens the circuit at any hour desired. This clock is much like the bank safe time lock now in use.

The cost of running the system is about 25 cents a month.

THE MAINE ELECTRICAL IMPROVEMENT CO.

The above company have secured the contract for the reconstruction of the power plant of the Brunswick Electric Light & Power Company, at Brunswick, Me. This plant is located on an island in the Androscoggin River. This island is a part of a rock formation in the bed of the river, forming one of the most beautiful cascades to be found upon the river, which is noted for its many waterfalls. Owing to the abundance of water power available and the advantageous position of this power plant, an unlimited amount of power can be secured for the uses of the many enterprises for which Brunswick is fast becoming prominent, and that, too, at a nominal cost. The variation in water level of the Androscoggin River during the different seasons of the year is nominal, and therefore the power secured therefrom is practically constant for all seasons of the year.

In a place such as Brunswick, located as it is within a stone's throw of "Casco Bay," which is one of the finest summer resorts upon the Atlantic coast, convenient to Portland, Bath, and others of the principal points in Maine, this electrical enterprise cannot but be a success, and the Maine Electrical Improvement Co. are indeed fortunate in securing so valuable a contract, embracing as it does a combination of electrical, mechanical, and hydraulic engineering.

THE BALL ENGINE CO.

The Ball Engine Co., of Erie, Pa., have the following letter from the Jeffrey Mf'g. Co. of Columbus, O.: "We have two of your 13"x12" automatic engines at the Helvetia mines, Helvetia, Clearfield Co., Pa. These engines are running two of our 80 horse power dynamos, generating power for transmission into the mines for the purpose of running our Jeffrey electric coal mining machines. The duty these engines are called upon to perform is very severe; perhaps more so than street railway work, for the reason that the load is thrown off and on by the short run of each engine and consequent sudden stop. We require a regulation for our work that shall not exceed a loss in revolutions of 2 per cent. The Ball engines at the above mines have been running about four weeks, and are giving entire satisfaction. They are noticed for their beautiful and solid construction, and the quietness and steadiness with which they run."

D. M. STEWARD MANUFACTURING CO.

The D. M. Steward Manufacturing Co., of Chattanooga, Tenn., write us: "We are pleased to report that the lava insulators are in demand to that extent that we are pushed to keep our customers anywhere nearly supplied. We ship goods to all parts of this continent and have to refuse orders for many shapes which we are not prepared to make. We are getting a great many letters from new customers, who credit THE ELECTRICAL ENGINEER with putting them in communication with us."

THE "WING" FANS AND PLANTS.

L. J. Wing & Co., 126 Liberty street, N. Y., write as follows:—

Trade has been good, especially in the East. We have added isolated lighting by electricity, through the use of small gas or steam engines, for private residences, stores, small hotels, etc.

The later developments in this class of machinery have made this system of lighting more economical than burning gas, while at the same time giving the comfort, beauty and safety of the electric light.

Among our sales for the past month we note: Jefferson Mfg. Co., Jefferson, Mass.; W. T. Henry & Co., Philadelphia, Pa.; John Simmons, New York, N. Y.; Manhattan Print Works, New York, N. Y.; Am. Carpet Cleaning Works, Brooklyn, N. Y.; U. S. Heating and Plumbing Co., Boston, Mass.; Judge Building, New York, N. Y.; Edison General Electric Co., New York, N. Y.; W. & J. Agate, Pittsford, N. Y.; Old Kentucky Cotton Mills, Louisville, Ky.; Russell & Morgan Co., Cincinnati, Ohio; Chelsea Jute Mills, Brooklyn, N. Y.; Ballard Vale Woolen Co., Ballard Vale, Mass.; W. H. Tolhurst & Son, Troy, N. Y.; Louisville Cotton Mills, Louisville, Ky.; Coombs, Crosby & Eddy, New York, N. Y.

THE AMERICAN ELECTRIC ELEVATOR CO.

The American Electric Elevator Co., of this city, have recently put in operation an electric elevator in the Grimes Building, Kansas City, which runs at a speed of 250 feet per minute, carrying an average load of 1,200 pounds with nine horse-power. This elevator is giving great satisfaction, and runs more smoothly and quietly than the average hydraulic elevator, and nearly equal to the very best hydraulic.

They are now installing a number of their elevators in various parts of the country, from Minnesota to Texas, and are at present installing an elevator in the Duquesne Traction Co.'s car house at Pittsburgh, Pa., for the purpose of raising the cars, a load of 10,000 pounds, from the tracks on the first floor to the paint shop on the floor above. This elevator is expected to be in operation in a few days, and will probably be the largest electric elevator at present in existence.

THE MONTREAL CONVENTION.

The provisional committee for the reception of the National Electric Light Association on their approaching visit to Montreal met on May 23, at the Windsor, in that city. The Governor-General has expressed the hope that he may be able to be present on the occasion if the visit takes place in September, and has announced that under any circumstances he will be glad to give his patronage to the meeting. It begins to be evident that the meeting will be a great success. President Huntley visited New York last week to confer with Secretary Beane about the various arrangements necessary.

NEW ENGLAND TRADE NOTES.

THE TROPICAL AMERICAN TELEPHONE CO., owner of the "Hynes" annunciator drop patent(No. 425,078), has begun suit in the U. S. District court in New York city against the Western Electric Co. and Irving Loveridge, its agent, for infringement of said patent by making and selling the "Hynes" annunciator drops used in switch-boards. Purchasers for home use or for export should buy these drops of the Tropical American Telephone Co. and avoid legal liability, as no other manufacturer has any authority to make or sell them. This drop is also known as the "Williams" drop.

THE REDDING ELECTRIC CO. have removed their executive and sales offices from 48 Hanover street to 41 Federal street, Boston, where all business will be transacted under the supervision of Mr. H. M. Nichols, secretary of the company. In their new premises they will have much more room to handle their rapidly increasing business, and be better able to handle promptly the demands of their customers. Large orders are already being received for Star Electrix goods and other specialties.

THE EVANS FRICTION CONE CO. have recently been turning their attention to the supply of their cones for producing variable speeds, which are peculiarly adaptable for wire mills, testing rooms, laboratory work, etc. Amongst their recent sales they have furnished goods to the following well-known companies: Taunton Copper Manufacturing Co., Taunton, Mass.; W. B. Tucker, Elizabeth, N. J.; Murray, Whitehead & Murray, Trenton, N. J.; Maschinen Fabrik Oerlikon, Zurich, Switzerland; Thomson Electric Welding Co., Lynn, Mass.; Thomson-Houston Electric Co., Lynn, Mass.; Electric Pipe Bending Co., Harrison, N. J.; Edison Electric Manufacturing Co., Schenectady, N. Y.; The Okonite Co., Passaic, N. J; Sawyer-Man Electric Co., New York; Washburn & Moen Manufacturing Co., Worcester, Mass.

THE BURTON ELECTRIC HEATER IN PRACTICAL WORK.

A RAILROAD COMMISSIONER in discussing methods of heating railway cars, recently said that electricity was as yet too dear to enter into the question. Similar opinion was expressed by a well-known electrician some weeks ago in regard to domestic heating. If in one field the mechanical appliances necessary are not yet so perfected as to admit of its adoption, and in the other the cost of current may be too great, yet for the heating of electric cars it has been thoroughly established that electricity is not only an agent theoretically perfect, but one whose use is economically practicable.

This has been demonstrated beyond the possibility of a doubt, by the application on electric roads of the Burton electric heater, the invention of Dr. W. Leigh Burton, of Richmond, Va. The history of this invention, in some respects remarkable, chronicles some marked triumphs, not unhampered, it is true, by the usual suspicion with which a new departure is regarded. For some years Dr. Burton had devoted much attention to electrical science and had carried on a long series of experiments with electric heaters. Beginning with the well-known fact that the heat generated in a conductor is proportional to the resistance of such conductor and the strength of current used, the problem was to devise some arrangement whereby the wires, when given current such as would heat them to a requisite intensity, would yet be in no danger of fusion. After much experiment, it was discovered that platinum or any wire of refractory material, even when of considerable length, if surrounded by finely powdered fire clay or similar substance, will, without danger of fusing, carry an electric current of such strength as would instantly destroy it if not thus surrounded. In this way the entire surface of the wire might be covered by a material which, although able to communicate the heat to the surrounding atmosphere, is of such high electrical resistance that it will not carry off a sufficiently large portion of the current to prevent its efficient action as a heat producer.

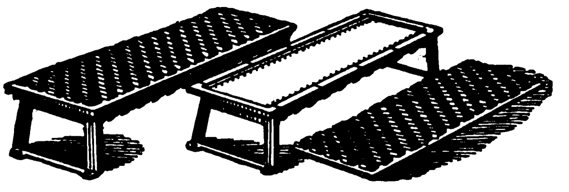


FIG. 1.

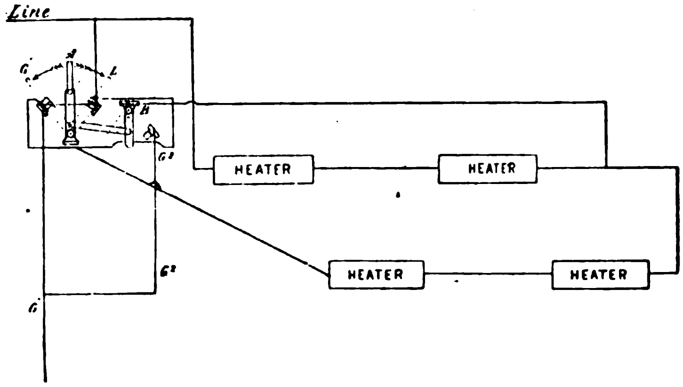

FIG. 4.

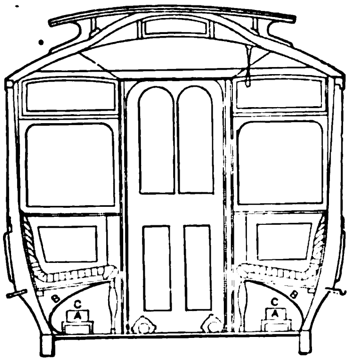

FIG. 2.

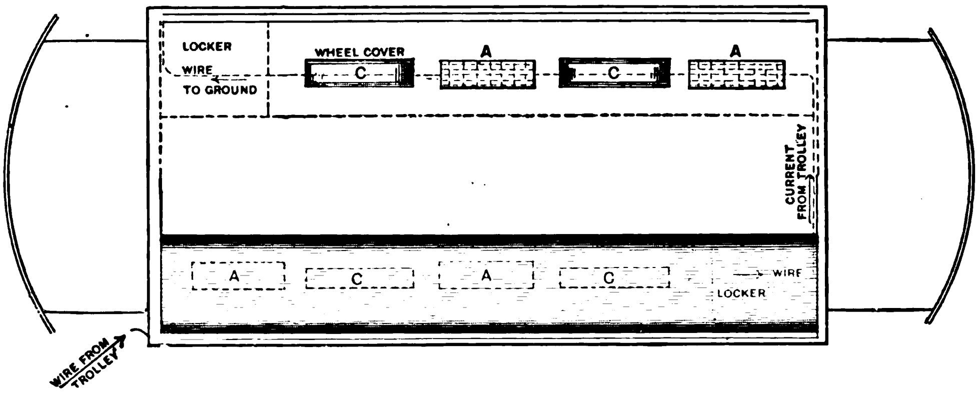


THE BURTON HEATER.

FIG 3.

A patent was granted to Dr. Burton upon the practical application of his invention in 1887, and some time later he secured another patent on an improved method of electrically connecting the heaters. Up to the present time, however, its use has been confined to electric cars. The apparatus used in street car work, and the method of wiring, will be readily understood by reference to the accompanying diagrams.

Fig. 1 shows the iron casing with a corrugated covering to facilitate the radiation of the heat, which contains the German silver wire stretched back and forth across the case and embedded in the fire clay. In wiring the ordinary street car, two such heaters are usually placed on each side under the seats, as shown in Figs. 2 and 3. The wiring is very easily done. Connection is made to the trolley wire in one corner of the car, and the current conveyed through the heaters under one seat and carried to the other side to a ground connection on the truck. The method of wiring adopted by the company is shown in Fig. 4, and for street car service the electrical resistance of the heaters is so adjusted that on a 450 volt circuit they use three amperes of current. When, therefore, the handle of the switch A is turned on L, a shunt from the line connection, and B closed, the heaters are thrown in series of two for a short time only, causing the use of six amperes of current in each set. When a sufficiently high temperature has been attained in these, which will be in fifteen or twenty minutes, the handle A is turned on G, ground connection, and B opened. This causes them to be thrown in series of four, when the heat will be maintained in them for a long time without being appreciably lowered, with the use of only three amperes of current.

The process of warming the cars is supposed to take place in the morning before the car leaves the shed, when there is no other use for the current. The normal use of the current, however, being only three amperes, the cost should be calculated on that basis.

As far as regards expense, it has been proved to the satisfaction of the officials on a number of roads, that it is fully as economical, and even more so when service and contingent expenses are considered, as the ordinary coal stove. Lieut. S. Dana Greene, the well-known electrician, who is consulting electrician for the Burton Company, estimates the cost to amount to less than 10 cents per day for each car, and in some cases, this estimate has been found too great.

The company are constantly in receipt of testimonials from various roads speaking of the heater in the highest terms as regards safety, comfort and economy. The patrons of the road using the heater are even more enthusiastic than the officials, and to any one familiar, by sad experience, with the dirty and gaseous condition of the average coal heated car, the absolute cleanliness and absence of odors, together with the even temperature of a car electrically heated, is a revelation in modern car heating.

The electric heater would find its warmest welcome, however, as a successor to that "deadly car stove" to whose account so many tragedies must be placed. Here the absolute safety of the electric heater should commend it, even though dividends were lessened somewhat by its use. By the employment of dynamos and storage batteries now carried on trains for incandescent lighting, the heater could be used, and the increased safety and comfort would more than compensate for any expense involved.

Other uses for the heater are innumerable and suggest themselves at once. With its almost ideal qualifications, its general application is warmly urged by those familiar with its operation, and, when once before the public, there can be no doubt of its rapid sale.

The John Scott legacy medal has been awarded the inventors for this electric heater on the recommendation of the Franklin Institute, of Philadelphia. The heaters are manufactured by the Burton Electric Company, Richmond, Va., for whom the Electric Merchandise Company, of Chicago, are selling agents.

A MAMMOTH MUNSON BELT.

At the invitation of the Charles Munson Belting Co., of Chicago, a party of gentlemen, among whom were some of the representatives of the technical and daily press, visited their factory to inspect a new belt of generous proportions which they are manufacturing for the Missouri Electric Street Railway Co., of St. Louis.

This enormous belt is no less than 72" in width, being one of the largest in the world. It is made of the very finest picked stock, and is of double leather 150' long, and capable of transmitting easily 2,000 h. p. Colonel J. H. Shay and Mr. Groetzinger, secretary of the company, explained the beauties of their pet, the excellence of the material, the fine finish in manufacture of the belt calling forth much commendation. It will belt direct from the engine to the line shaft in the station, which is equipped with the famous Hill clutch pulleys. All of the shafting work, which is of the very highest class of work, has been installed by the Hill Clutch Works, of Cleveland.

The Munson Belting Co. have already furnished two 54" double leather belts for the same plant, 140' each in length, and 860' of 16" belting, which is used for driving the generators. With the order for the monster belt was included a further order for two generator belts, 84" wide and each 74' long. All these belts are noticeable for the excellence of the workmanship, and their immense strength and durability.

NEW YORK NOTES.

Mr. W. S. Turner, of the Woodbridge & Turner Engineering Co., has married Miss Helen Sewall, of Clarinda, Ia.

Mr. T. J. Murphy, of 96 Columbus ave., this city, is in direct connection with one of the finest slate quarries in the country, and furnishes slate for all electrical purposes, such as switchboards, switches, fusible cut-outs, resistance boards, etc. As an evidence of the work which he does, mention might be made of a large order which he recently executed for a New York concern. The slate was in pieces of 22 square feet, 5-8 inch thick, each piece pierced with 12,000 holes, ¼ inch and ¼ inch apart. He sends without charge by express a sample of finished and unfinished slate, and invites a chance to quote on quantities of any goods in his line.

Mr. E. Gabel, formerly with the Munson Belting Co., will respresent the Page Belting Co. hereafter in this city.

Walton E. Crane, manufacturer of the popular "Common Sense" oil filter, of Minneapolis, Minn., has removed to New York, and is located at Nos. 9 and 11 West 13th street. His filter business has been growing so fast that it has become necessary to have an Eastern office and shipping point for the Eastern trade, and also to accommodate his rapidly growing export trade. The "C. S." oil filters seem to introduce themselves, wherever electric plants are established, and that means nearly all over the world. The reversed gravity, submerged filtering material, and visible operation of this filter have secured for it the warmest admiration and praise from its purchasers and users.

E. G. Bernard & Co., electricians, etc., of Troy, N. Y., have received the contract for electrical supplies for the house of Hon. Levi P. Morton, at Rheinbeck, N. Y.

PHILADELPHIA NOTES.

The Equitable Engineering & Construction Co. have secured the contract for the construction of the Lebanon & Annville Electric Railway, Lebanon, Pa. Mr. S. Ashton Hand has been elected vice-president and mechanical engineer. Mr. L. K. Perat, formerly of the Thomson-Houston Co., Lynn, has joined the force of the Equitable Engneering Co.

The Heisler Electric Light Co., of this city, have just installed plants of their Long Distance Series Incandescent Lighting at the following cities: Montgomery, Ala.; Colorado, Texas; Montpelier, Vt.; Saltillo, Mexico; Norwalk, Ohio, and Port Richmond, S. I. They have received orders for their new series lamps for use on arc light circuits, which will require over three months to fill.

Baltimore, Md.—Messrs Kingsbury & Mustand have the contract to equip the New National Theatre, at Washington, D. C., with 650 incandescent lights of the Edison three-wire system.

Mr. Henry A. Reed, of the Bishop Gutta Percha Co., New York, was in this city last week and contracted with the West End Electric Co. to furnish all the cables used in their large plant now under construction.

Norwalk, Ohio.—The Howe Construction Co. are increasing their plant with 700 32 c. p. lamps of the Heisler system.

WESTERN TRADE NOTES.

Mr. W. L. Adams, who has been associated with the Northern Engineering Co., of Buffalo, has joined the forces of the Electric Merchandise Co., of Chicago. Mr. Adams is a thoroughly practical man, and has a large acquaintance among street railway men. He will represent the company chiefly in the East, where he will look after their rapidly growing business, and introduce to street railway men all the new and valuable specialties which they are continually producing.

Mr. D. B. Dean, traveling representative of the Electric Merchandise Co., has just returned from a highly successful trip, and will leave in a few days for the Pacific coast in the interests of his company.

The Electric Merchandise Co., through their energetic representative, Mr. D. B. Dean, have recently closed a contract with the Williamsport Passenger Railway Co., of Williamsport, Pa., for all their necessary line material and supplies, for the equipment of six miles of road.

Mr. Henry C. Eddy, who recently resigned his position as Western manager of the *Electrical World*, has associated himself with the *Street Railway Journal*, and will look after the interests of our esteemed contemporary in the West.

The National Construction Co., 119 to 121 La Salle street, are going to build a new electric light plant on Dearborn street. The work is in the hands of Mr W. L. Abbott, manager of the above named company, and under his supervision, and will be one of the most complete plants in the country.

The Illinois Electric Material Co. are having a fine run on their general electrical supplies and the various specialties they handle, and are doing a prosperous and growing business.

Mr. Charles E. Brown, the traveling representative of the Central Electric Co., has returned from a Western trip, the results of which have been exceedingly satisfactory in the shape of numerous orders for their valuable supplies and specialties of all kinds.

Mr. Jas. H. McGraw, president of the *Street Railway Journal*, has been spending some days in Chicago and was a caller at the Western office of The Electrical Engineer last week.

Mr. S. W. Trawick, of the St. Louis office, of the Westinghouse Electric Mfg. Co., was in town last week.

The new restaurant service of the Chicago Electric Club was most successfully inaugurated last week with a very elegant table d' hote lunch, and everything is now in fine running order. The simplest lunch to the most elaborate dinner can be obtained at the club. These desirable results have been obtained by the indefatigable efforts of Mr. W. B. Pearson, chairman of the Board of Managers, assisted by his able lieutenant, Mr. W. P. Sullivan, the manager of the club, and the united thanks of the electrical fraternity are due to Mr. Pearson for the able manner in which he has handled things, and devoted so large a portion of his time for some while past to the work.

Thwing Electric Co.—The sale of the property of the Thwing Electric Co., Lake and Peoria streets, Chicago, has been postponed till June 8th, and the prospect is very fair indeed that the business of the company, which is the manufacture of a perfected incandescent lamp, will either be carried on by a reorganization, comprising some of the old officers, or by new parties.

Mr. Frank McMaster, who has been associated for some time past with the Chicago Edison Co., has accepted a position as electrician of the Chicago Electric Motor Company, who are manufacturing large numbers of motors of all sizes, for fan purposes and all kinds of electrical work. Mr. McMaster will assist Mr. B. D. Southard, manager of the above mentioned company, in designing the machines, paying special attention to the electrical part of them, Mr. Southard, who is a well known mechanical engineer, looking after the mechanical design. Mr. McMaster is an energetic, well posted electrician, and his experience in this line will be of material service to the company.

Mr. H. M. Underwood, the energetic western agent of The Interior Conduit & Insulation Co., is rapidly introducing their well-known and valuable system in the West. He has already secured some large contracts, and has a number of important deals on hand.

Paiste. A large consignment of the well and favorably known Paiste specialties, has been received at the Western office of H. T. Paiste, 341 The Rookery, which is in charge of Mr. Thomas G. Grier, the well-known mechanical and electrical engineer.

Mr. Fred Calkins, of F. W. Calkins & Son, has just sold a 1,000 light incandescent machine of the Mayo system.

☞ Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Miscellaneous, etc., will be found in the advertising pages.

THE
Electrical Engineer.

VOL. XI. JUNE 10, 1891. No. 162.

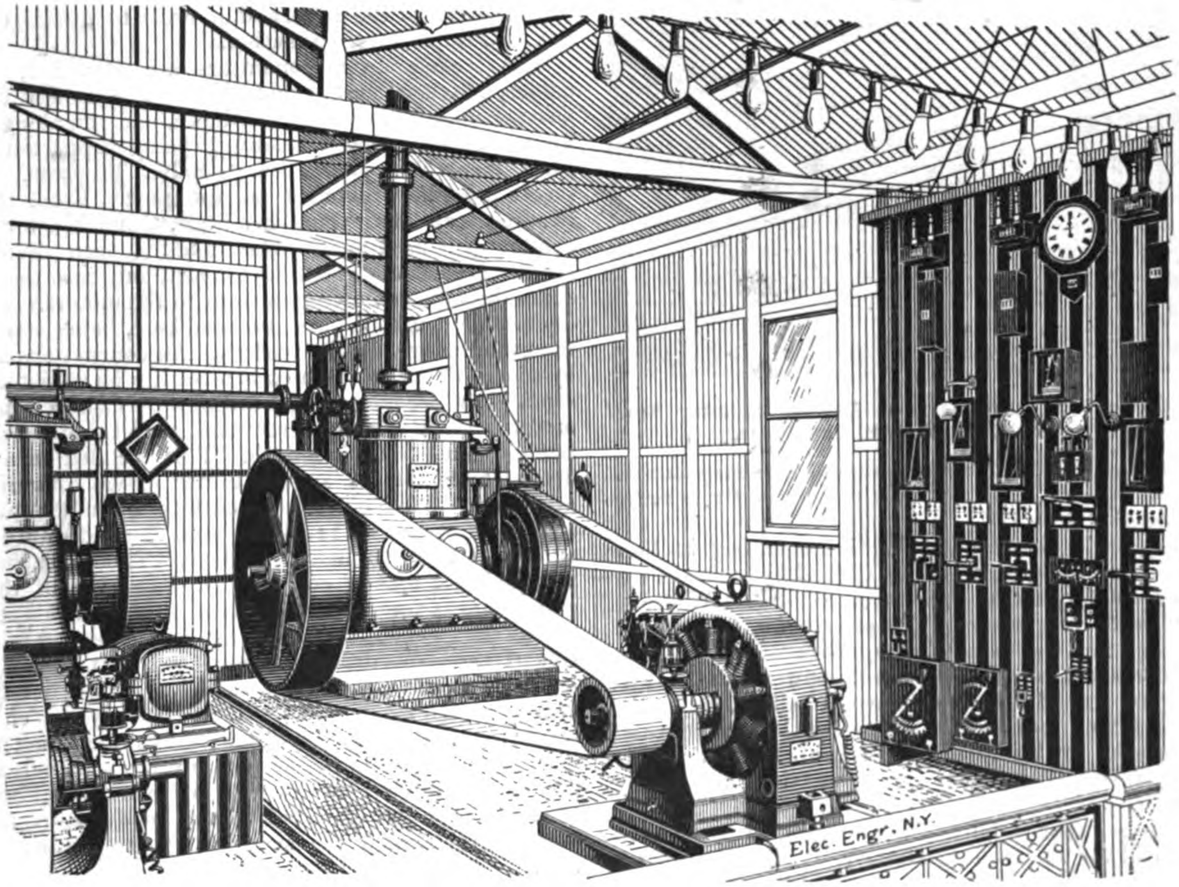
ELECTRIC LIGHT IN AUSTRALIA.

BY

Arthur C. Lovett.

AS a regular reader of THE ELECTRICAL ENGINEER, it has occurred to me that a few items in connection with lighting in Australia may be of interest to your readers.

We have three towns lit by Thomson-Houston plants, namely, Young, Lambton, and Penrith, and one on the Westinghouse system. The installations are all comparatively small, but it is a start in the right direction.



Elec. Engr. N.Y.

FIG. 1.—ELECTRIC LIGHT STATION, WESTINGHOUSE SYSTEM, NEWCASTLE, NEW SOUTH WALES, AUSTRALIA.

The installation at Newcastle, which is the first Westinghouse plant installed in Australia, was opened early in January last, and is shown in the accompanying engraving, Fig. 1. There are two 750 light 1,000 volt alternating current dynamos with separate exciters, both dynamos and exciters being driven direct from the engines. The engines, of which there are two, are of the well-known Westinghouse type, indicating 75 h. p., supplied with steam at 120 lbs. pressure from two Babcock & Wilcox boilers.

In addition to these, which are for the incandescent circuits, there is a Brush arc light dynamo driven by a smaller Westinghouse engine of about 25 h. p. The usual Westinghouse street system is used for the street circuits, the incandescent lamps, which are 50 volt, being run in multiple arc in groups of 20 in series. There are at present 400 incandescent lamps on the street circuits.

In Hunter street, the principal thoroughfare, there are 23 Brockie-Pell arc lamps suspended by cross wires in the centre of the street as shown in Fig. 2.

The cables, which are Callender's throughout, are all overhead. There has been a good deal of friction with the authorities of the telegraph department as to the rather haphazard way in which they cross the telegraph wires without any guard wires.

The switchboard is a very handsome one and is mounted on colonial woods. On the switchboard there is a novelty to us in Australia in the shape of cut-outs having a platinum wire indicator.

The work was carried out for the contractors, Messrs. Westcott, Marshall & Adams, by Mr. E. J. Erskine, under the supervision of Mr. G. Hitchcock, of the Westinghouse company.

Additional interest is added to this installation by the fact that so close to it, at Lambton, which is a suburb of Newcastle, we have a Thomson-Houston plant, which has been in operation since September 10, 1890.

There two 650 light Thomson-Houston alternating current dynamos driven by two Fowler's engines of 65 h. p. each. There are two locomotive boilers supplying steam at 140 lbs. pressure. The street circuits are four in number, each circuit consisting of forty 25 candle power 25 volt lamps run in series.

The house circuits at present only take up about 400 lights, but the demand is rapidly increasing.

The contractors were Messrs. H. H. Kingsbury & Co., the agents for the Thomson-Houston Co. Messrs. Kingsbury have installed almost identical plants at Penrith and Young. The Young installation has been running since March, 1889. The installation at Penrith was opened in August, 1890. I may state that the population of Young is only 2,300 and that of Penrith 3,000; Lambton, the installation of which was opened on September 10, 1890, has 6,000 and Newcastle, 14,000 inhabitants. We have but one electric street railway in New South Wales, and that is a short length of about one mile and a quarter beteen Randwick and Waverley, two of the Sydney suburbs. It is on the Thomson-Houston overhead system, and was erected for the Government by Messrs. Kingsbury & Co. The line is a very stiff one having a lot of steep gradients on sharp curves. There are three cars fitted up, of which one only is being used at present.

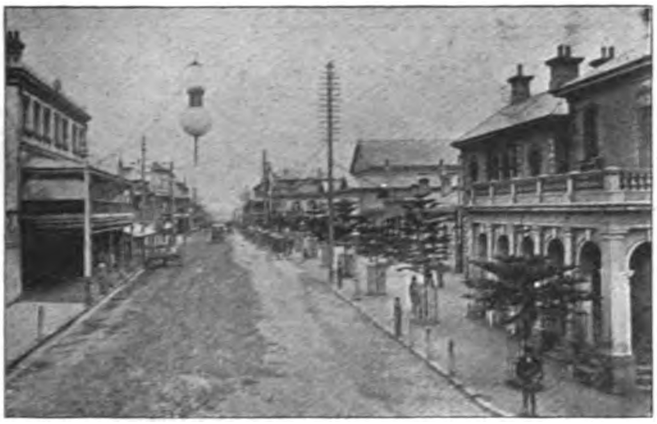


FIG. 2.—BROCKIE-PELL ARC LAMPS ON HUNTER STREET, NEWCASTLE, NEW SOUTH WALES, AUSTRALIA.

In Sydney itself, electric lighting is beginning to look up. The contract for the lighting of Redfern, one of the suburbs nearest the city has been awarded to the Williamson Electrical & Engineering Company, who, I hear, are contemplating putting in a Westinghouse plant. There are to be 400 street lamps of 25 candle power each. The price tendered was £10,326 exclusive of poles, which the corporation intend putting in themselves. The contract has also been let for Beewood, another suburb of Sydney, to Messrs. Wood Bros., who intend putting in Mordey alternators.

Half-a-dozen other suburbs have combined and have decided to call for tenders immediately. The city fathers themselves have also been considering the matter for some time, and have practically decided to form a small committee of experts to advise them in the matter.

A good many of the country towns, fired by the energy evinced at Young, Lambton, etc., are all eagerly going into the pros and cons of the question. Goulburn, Albury, Grafton, Glen Innes, Maitland, and others too numerous to mention, are all deeply involved in considering volts, ohms and amperes.

ELECTRICAL HANDLING OF PLATE GLASS.

An interesting application of electric power has been made at the Pittsburgh Glass Works, at Ford City, Pa., where a motor is used for hauling the polishing tables about the factory. The operation of the motor is said to be very satisfactory. The table with glass in place weighs 15 tons. It is expected that this initial plant will be followed up by a number of others.

ELECTRIC MINING AT BROWNSVILLE, PA.

BY ALFRED E. BRADDELL.

As a means of saving labor and time, electricity is now rapidly coming to the fore to replace, in a great measure, the pick and shovel in coal mines. A plant has recently been installed in the mines operated by the Redstone Oil, Coal and Coke Co., situated near Brownsville, Pa. The plant consists of a United States generator (80 h. p.) 250 volts, driven by a 200 h. p. engine made by C. C. Cooper, Mt. Vernon, Ohio, with two boilers manufactured by the Altoona Mfg. Co., of Altoona, Pa.

The generator is not driven direct from the engine but from counter-shafting. The fly wheel of the engine is 142½ inches in diameter, which is belted to a pulley of 42 inches diameter, placed on one end of the counter-shaft. On the other end of this is a pulley 60 inches diameter, which in turn is belted to a 30 inch pulley on the generator. The motors were manufactured by the Jeffrey Mfg. Co., of Columbus, Ohio, there being two in operation at the present time. These motors are of very solid construction in order to withstand the rough usage applied to them by the miners, as they have necessarily to be shifted about to the various parts of the mine, and, in order to do this, crowbars, etc., are called into requisition.

The feeders from generators are stranded, insulated cables, No. 0000 B. S. each. These are brought down the shaft, which is 280 feet in depth, and run along what is known as the "main heading," being supported on large glass insulators placed on wooden brackets, the opposite poles kept about 8 inches apart. From this main heading run the "butt headings," and No. 0 B. S. bare conductor is used here. The mine is then divided into rooms placed about 33 feet apart, and into these rooms come the taps conveying current to the motors. Bare conductors (No. 2 B. S.) are also used here, being supported in the same manner as the feeders. All connections are made by means of clamps, which can readily be adjusted, at the same time securing a good contact. Connection to the motor is made through a stranded twin cable heavily insulated, about 100 ft. in length. This is coiled on a reel or drum which rotates as the motor moves forward during operation. This operation consists of under-cutting the coal by a series of revolving teeth for a distance of 6 ft. and about 18 to 20 inches in width. This is calculated to be equal to 4 tons of coal, and on timing one of these machines it was found to have taken exactly 4 minutes to do the work. When the machine has under-cut along one side of the room the coal is blasted so that it can then be easily removed with the shovel. Three men are in charge of the machine, and it is certainly an engrossing sight to watch these unskilled toilers handling, with the greatest of ease and the utmost indifference, such a powerful, yet unseen, force. It was, in truth, a verification of the saying: "You push the button, we do the rest." These men simply turned the switch and the current did the rest.

ELECTRICITY APPLIED TO ORGANS.

Mr. Hope Jones, of Liverpool, who has already built and used an electric organ, stated to the College of Organists, the other day, that he was confident that he could construct an organ without bellows, sound boards, or even pipes, the sound being produced by electricity. Stop-knobs he has already abolished, a touch of an electric knob instantly putting the stop in or out of operation. He has also devised a "transposing switch," by which the music as it is being played can instantly be transposed to any higher or lower key by the action of electricity.

DOBBIE'S GEARLESS ELECTRIC LOCOMOTIVE.

BY

Robert P. Dobbie

THE prominence that the rapid transit question now occupies in the public mind, renders anything bearing on its achievement of special interest. The needs of the times are fast making the horse car a thing of the past, and even the higher speed of the electric street car falls far short of the actual requirements of to-day.

The impracticability of gears for anything like high speed—for instance, from 30 to 60 miles per hour—and the certainty that, if the armature were placed on the axle direct, the vibration would insure disaster to any known insulation, caused the writer to devise a means by which all the advantages of direct connection could be gained, and at the same time retain the well-known action of springs to obviate or suppress vibration.

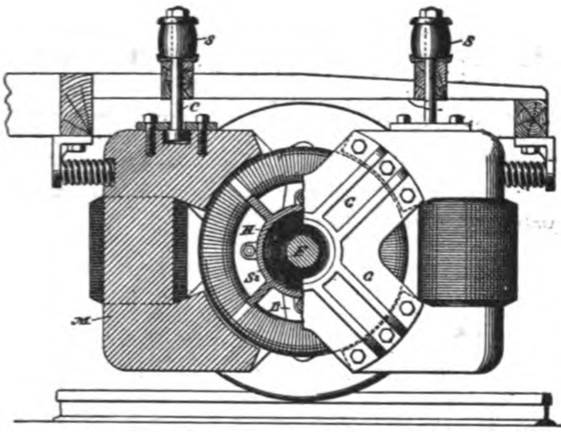

FIG. 1.—DOBBIE'S GEARLESS ELECTRIC LOCOMOTIVE.

My ideas as to how this should be done have been embodied in an arrangement, shown in Figs. 1 and 2, in which the desirable combination of spring suspension and direct coupling are attained by the use of a sleeve H concentric with the axle F. Upon this the motor is mounted,—the armature by the usual spider or other device, and the field magnets by bearings G. At the ends of this sleeve are cranks and crank pins which are coupled to a crank pin of similar radius (in relation to the centre of axle), by a link L, which assumes a position parallel to the tangent of the armature or wheel periphery. Between the axle and sleeve are interposed rubber or other springs or cushions, to prevent the possibility of the axle striking the sleeve by a severe jolt caused by faults in the track.

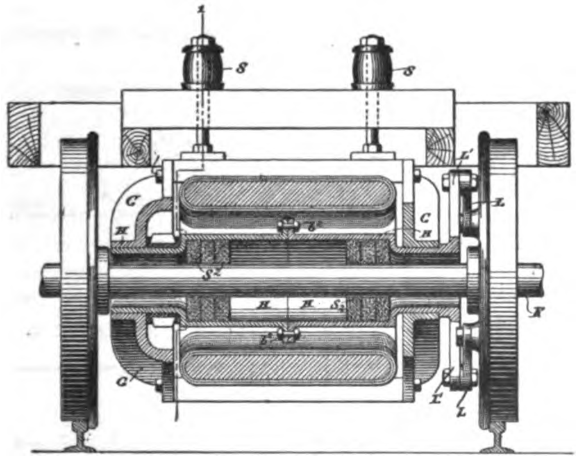

FIG. 2.—DOBBIE'S GEARLESS ELECTRIC LOCOMOTIVE.

This whole system of armature, field magnet, and sleeve, is supported by springs s s, so that there is no weight placed upon the springs or cushions s' under normal conditions, but in construction of small motors, as shown in Fig. 3, all other supporting springs could be dispensed with, reliance being placed on the rubber springs entirely. In this case, however; cross-tie rods D' should be used to counteract the tendency of the field magnets to rotate in a direction opposite to that of the armature. Lateral motion is taken up by springs between sleeve and wheel mounted on the frame so as to act when a lateral strain occurs, as, for instance, in going around a curve. Having thus described the principles, it would be interesting to give an outline of the weight, speed and power by an example.

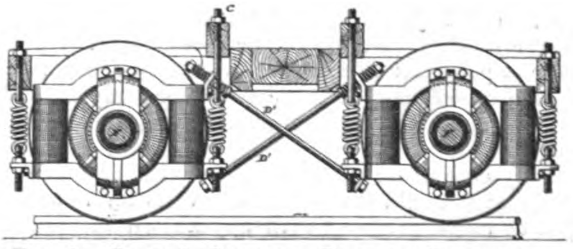

FIG. 3.—DOBBIE'S GEARLESS ELECTRIC LOCOMOTIVE.

Referring to Figs. 1 and 2, these show one motor and a pair of wheels 42 inches in diam.; the armature is 30 inches long by 30 inches in diam.; this being about the largest possible with this size of wheel, and a 4′ 8½″ gauge. This is placed in a four-pole field specially designed with reference to the clearance of the roadway and protection of coils, and connected by bronze castings G.

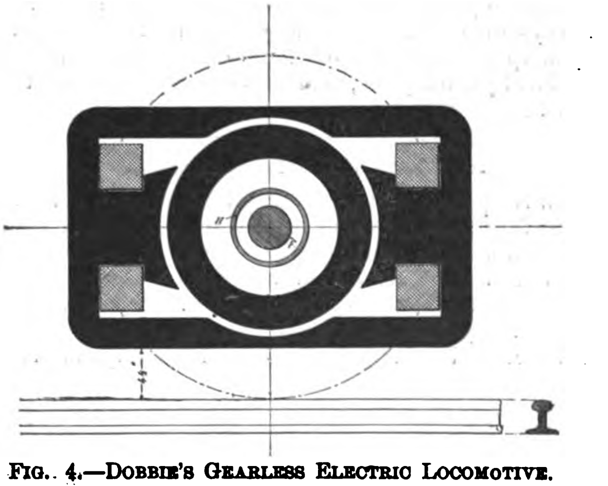

FIG. 4.—DOBBIE'S GEARLESS ELECTRIC LOCOMOTIVE.

Fig. 4 shows another design that has many recommendations. It is of the so-called Kennedy type and is drawn to scale for a 15 h. p. motor on a street car axle, designed to run at 110 rev. per min. Although its weight would be greater than a high speed motor of the usual pattern, the absence of gear wheels with their frames, etc., makes the difference less than would appear at first sight, and this disadvantage is more than made up by the absence of noise and loss in transmission.

Returning to Fig. 1, the power of this motor, running at 60 miles an hour, (which would be 480 revolutions per minute for the armature) would be 150 h. p. and this could easily be developed. The clearance between the axle and sleeve is 2 inches; the diameter of the axle 6 inches. The whole weight of motor and truck frame is approximately 14 tons (of 2,000 lbs.) and is sustained by journals F outside of the wheels. Two such motors on a truck would more than equal the performance of the present elevated railroad engines, and disposes of the many objections to steam locomotives on urban and suburban railroads, so ably pointed out by Mr. Sprague in his paper before the American Institute of Electrical Engineers. A locomotive with two such trucks, weighing about 56 tons in all, and developing 600 h. p., would take the train to Philadelphia in "limited" time.

There is in this estimate nothing in the nature of an extraordinary motor giving abnormal power for its weight, but it is just a plain statement of possibilities with good electrical engineering of the present day. Upon such a motor a potential of 2,000 volts could be used, and the insulation relied upon, as there would be complete suppression of the small and rapid vibration inseparable with high speed.

It is my conviction that no motor with armature direct upon the axle would stand even 500 volts for 10 hours running at 60 miles per hour with any known insulation that could be applied, and I believe as firmly that a motor suspended by springs, as shown, is capable of fulfilling the more exacting requirements mentioned.

STEAM AND ELECTRICAL DISCHARGE.

At the last meeting of the Royal Meteorological Society, Mr. Shelford Bidwell, M.A., F.R.S., exhibited an experiment showing the effect of an electrical discharge upon the condensation of steam. The shadow of a small jet of steam cast upon a white wall is, under ordinary conditions, of feeble intensity and of neutral tint, but if the steam is electrified the density of the shadow is at once greatly increased, and it assumes a peculiar orange-brown hue. The electrical discharge appears to promote coalescence of the exceedingly minute particles of water contained in the jet, thus forming drops large enough to obstruct the more refrangible rays of light. It is suggested that this experiment may help to explain the intense darkness, often tempered by a lurid yellow glow, which is characteristic of thunder clouds.

THE FRANKFORT EXHIBITION.

The Allgemeine Elektricitäts-Gesellschaft and the Maschinenfabrik Oerlikon have now definitely undertaken to contract for transmitting power electrically from Lauffen to Frankfort, and are bound under heavy penalties to finish the work at the latest by August 15th. There is, therefore, no longer any doubt but that this important experiment, the successful issue of which will greatly interest the scientific world, will soon be an actual fact.—*Elektrizität*, the official journal of the Exhibition, is profusely illustrated, and contains a large amount of useful information on subjects connected with electricity in general and its display at the Frankfort Exhibition.—The committee of the Exhibition have decided to reserve a special building, to be opened on June 15th, for a collection of plans, projects, and results of central station working, which they think will be useful, not only in connection with the Municipal Congress but to the general visitor.

CENTRAL STATION MANAGEMENT AND FINANCE.—VI.

BY

Horatio A. Foster

Pay Roll Department.

In most stations very little attention is given to classification in this department, but much good will come of doing so, as only in such methods can any accurate calculation of costs be made.

[Form 15.] Copyrighted 1891.

____________________ Company.

____________________ *189*

Time Card for 24 hours ending 7 o'clock, A. M., this date.

THIS CARD MUST BE IN OFFICE BEFORE 8 A. M.

Name, ____________________

Occupation, ____________________

Order Number.	Hours Regular.	Hours Extra.	Rate.	Amount.

Approved,

____________________ *Foreman.*

Blank No. 15.—Employees' Time Card.

Although not absolutely necessary for those persons employed on the usual routine work, such as firemen, dynamo oilers, storekeeper and clerks, and some few others who work on salary, every employee should be compelled to turn in a time card every day, with the time devoted to different jobs stated under the regular order number and countersigned or approved by his foreman or chief. Only in this way can disputes as to the man's pay and the cost of work be surely settled.

Any neglect of the man is sure to be made up and to cease after a few losses of pay.

[Form No. 16.] Copyrighted

PAY ROLL for week ending ____________________ *1891.*

We, the undersigned, have this __________ *day of* __________ *1891, received the amount set against our respective names in full payment to date.*

NAME.	Number	OCCUPATION	Days	Rate	Operating	Outside Construction	Inside Construction	Amount Due	Number	SIGNATURE.

Blank No. 16.—Pay Roll Receipt Blank for Employees.

Form No. 15 works well for this, and when on construction or repairs the results are easily posted in the proper order or cost book. For ordinary station work, it will be found sufficient to divide the time books and pay roll into, say, three different accounts, viz.: "Operating, pole line construction, and inside wiring." Then in entering the pay roll in the cash book, the items can be stated under their different heads and posted to the proper account. Form No. 16 has been found sufficient to fit the case. Time books of various good forms can be had of any stationery store.

ELEMENTARY GEOMETRICAL THEORY OF THE ALTERNATE-CURRENT TRANSFORMER.—II.

BY

Chas. Steinmetz.

A preliminary magnetic test of the iron to be used, which can now be carried out easily, will give the magnetic constants of the kind of iron we have. Good magnetic conductivity of the iron must be considered as of far less importance than low hysteresis. But here, in designing transformers, a certain consideration comes in, to which, so far as I know, attention has never yet been drawn, namely, whether the transformer has to be used as a *parallel converter* in a *constant potential system*, or as a *series converter* in a *constant current circuit.*

In the constant-potential transformer, the magnetization, and therefore the iron loss, is almost constant all day, no matter whether the transformer is running light, or whether it is overloaded. Therefore, if the iron loss is not very small, it will run up during the day quite considerably, and in spite of a very high efficiency for full load, the all-day efficiency will be found low. Here the heating loss in the copper is of very much less importance, because it amounts to an appreciable quantity only for full load, and decreases proportionally to the square of the load, so that it shows up rather small, in the all-day efficiency, and a transformer of considerably smaller full-load efficiency can be far more economical in continous run than a transformer which is highly efficient only for full load. Hence, in a constant-potential transformer the iron loss ought to be lower than the full-load copper loss, which I know is not always the case.

Quite different conditions, however, are met with in a constant-current transformer, which, when not loaded, is short-circuited. Here the heating loss in the copper is almost constant, and if not very small, will decrease the all-day efficiency considerably (if the converter is in circuit all day). But the iron loss varies with the load, and amounts to an appreciable quantity only for full load, being, as supposed, about proportional to the 1.7th power of the magnetization, that is, in this case, of the load. Therefore a comparatively light loss of energy in the iron will be of less importance in a constant-current transformer.

For constant-potential transformers a rather low magnetization, of about 20,000 to 30,000 lines of magnetic force per square inch, is generally used, in practice, and even this is very likely still too high for economical all-day work with the usual frequency. In Europe, where a much lower frequency ($N = 42$ for instance, Ganz & Co.) is used, the magnetization is somewhat higher, too, and nevertheless, the percentage of iron loss smaller.

But not only is the loss of energy in the transformer, in the iron and in the copper, of importance for its efficiency, but sometimes, especially in large transformers, still more consideration is needed for devising means to carry off the heat generated in the iron and copper; for the transformer is not like the dynamo, which, revolving with high speed, produces a powerful air-blast even with a smooth armature, and thereby radiates a large amount of heat per square inch of surface. The transformer, on the contrary, is entirely at rest, compact, and of small surface in comparison with its volume, and generally enclosed in an air-tight casing, and therefore no air current can be relied upon for radiating heat. Hence a much larger radiating surface is needed per watt of heat in transformers than in dynamos.

Let us, for instance, assume the *field intensity* of the transformer treated as an example, to be as a maximum, $H = 20{,}000$ lines per square inch. Therefore the *iron cross-section* needed to carry the 200,000 lines used for producing the intended induction, is:

$$q = \frac{M}{H} = \frac{200{,}000}{20{,}000} = 10 \text{ square inches.}$$

Let the *output of the transformer*, for full load, be = 2,500 watts.

Then, the *secondary* E. M. F., being $n = 70.7$ volts effective, we get the *secondary current* = 35.35 amperes effective,
and the *secondary resistance* for full load:

$$R_1 = \frac{70.7 \text{ (volts)}}{35.35 \text{ (amperes)}} = 2 \text{ ohms.}$$

Hence the *primary current* for full load is somewhat larger than: $\frac{n_1}{n} \times 35.35 = 26.5$ amperes effective.

From this, with due consideration of the drop of potential permissible for full load, and of the carrying capacity of the transformer wires, we get the cross-section of the primary and of the secondary conductor, and therefore the *length of the magnetic circuit.*

Let $l = 12$ inches, be the average length of the magnetic iron circuit.

Where exact calculation is intended, it must be borne in mind, that the "*average length*" of a magnetic circuit is not the *arithmetical* mean, but the *harmonic* mean of the different lengths in the different parts of the cross-section, that is, the *inverse value of the mean of the inverse values* of the different lengths, or:

$$l_h = \frac{q}{\int_0^q \frac{d\,q}{l}},$$

as everywhere, where conductors of different length are joined in parallel into an electric or magnetic circuit.

This harmonic mean, however, will generally be near enough to the arithmetic mean,

$$l_a = \frac{1}{q} \int_0^q l\,d\,q, \text{ to be replaced thereby.}$$

In a small Westinghouse converter I found the difference to be only 2 per cent. in favor of the *harmonic mean*, this always being *smaller* than the *geometrical* mean and this again *smaller* than the *arithmetical* mean.

Then the whole *magnetic resistance* of the iron circuit is:

$$P = \frac{\rho\, l}{q},$$

where: ρ = the specific magnetic resistance of the iron ($\mu = \frac{1}{\rho}$, its magnetic susceptibility).

Assuming $\rho = .01$,[1]

we get: $$P = \frac{.01 \times 12}{10} = .012.$$

That means: F ampere turns produce $\frac{F}{P}$ lines of mag-

---

[1] This figure, like the others, is intentionally chosen such that the secondary terms, as drop of potential, exciting current, etc., are large enough to be easily shown in the small scale of the diagram. In reality ρ will be less than .001.

netic force in this magnetic circuit. Hence, to produce the magnetic current, $M = 200{,}000$ lines,
$F = M \times P = 200{,}000 \times .012 = 2{,}400$ ampere turns M. M. F. are needed.[1]

II. Transformer Diagram.

The maximum M. M. F. in the transformer under consideration was : $F = 2{,}400$ ampere turns.

Hence the M. M. F. at the the time, t is :

$$f = F \sin 2\pi N t = 2{,}400 \sin 2\pi N t\,;^{2}$$

where $N = 133 = \frac{1}{T}$ = the number of complete periods

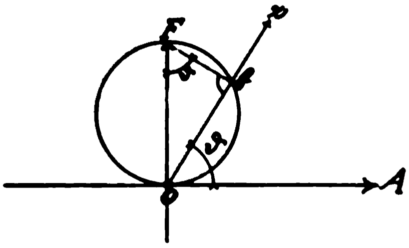

FIG. 1.

per second, and we begin to count from the time where: $f = 0$.

Let the angle, $2\pi N t = \frac{2\pi}{T} t$ be denoted by θ ;

the time $T = \frac{1}{N}$, of one complete period will therefore be represented by one revolution, or the angle, $2\pi = 360°$.

Then we can produce graphically the M. M. F. acting at any time, t, that is, at any angle, $\theta = 2\pi N t$, in a *system of polar-co-ordinates*, by assuming, in Fig. 1, a line $\overline{OA}$ as zero line, producing $\overline{OF} = F$ and perpendicular to $\overline{OA}$, and drawing a circle with $\overline{OF}$ as a diameter.

The whole revolution of a radius-vector, from the zero line $\overline{OA}$ back again to $\overline{OA}$, represents a complete period; any time, t, is represented by an angle, $AOx = \theta = 2\pi N t$, and the M. M. F. working at the time, t, that is, the angle $AOx = \theta$, is cut out on the very radius $\overline{Ox}$ of the angle θ, by its intersection with the circle with $\overline{OF}$ as a diameter, so that *this circle represents the curve of the* M. M. F. *in the polar-co-ordinate system.*

For : $\overline{Of} = \overline{OF} \sin \theta$; that is, $f = F \sin 2\pi N t$.

This representation of harmonic functions is by far more convenient than the representation in rectangular co-ordinates, by a wave line, because it shows directly the periodicity, and *represents the harmonic wave by an elementary curve, the circle.*

In the same way any other, not sinusoidal, wave can be represented by a closed unicursal curve, as we shall show further on.

As we have seen, for :

$\theta = 0$, that is, $t = 0$, the M. M. F. is : $f = 0$.

$\theta = 90°$ that is $t = \frac{T}{4} = \frac{1}{4N}$, the M. M. F. is : $f = F$.

$\theta = 180°$ that is $t = \frac{T}{2} = \frac{1}{2N}$, the M. M. F. is: $f = 0$ again.

$\theta = 270°$ that is $t = \frac{3\,T}{4} = \frac{3}{4N}$, the M. M. F. is : $f = -F$, because the circle of M. M. F. intersects the radius in its prolongation on the opposite side of o, and for $\theta = 360°$, that is, $t = T = \frac{1}{N}$, the M. M. F. is again, $f = 0$. Hence the circle, which represents the sine wave, is produced twice during each period.

In the diagrams, Figs. 1 and 2, we assumed 1 ampere turn = .0003 inch ; therefore, $\overline{OF} = 2{,}400$ ampere turns = .72 inch.

In the same way, we produce, in Fig. 2, the *secondary* E. M. F., e_1 graphically.

This is a maximum at the time at which f decreases most rapidly, that is, for $\theta = 180°$; or, $t = \frac{T}{2}$, and is then $E_1 = 100$ volts, as assumed.

Now, let 1 volt = .01 inch ; then the *secondary* E. M. F., e_1 is represented by a circle with :

$E_1 = \overline{OE_1} = 1.00$ inch in diameter.

This circle cuts out on any radius the instantaneous value of the secondary E. M. F. For instance, to the time, $t = \frac{T}{6}$, there corresponds an angle :

$$\theta = \frac{2\pi}{T} t = \frac{\pi}{3} = 60° = \text{angle } AOx,$$

and its radius $\overline{Ox}$, intersecting circle $\overline{OE_1}$ at e_1 gives at that moment the secondary E. M. F.:

$$\overline{Oe_1} = -.5 \text{ inch} = -50 \text{ volts.}$$

The M. M. F., $\overline{Of} = .623$ inch = 2,078 ampere turns.

As the maximum value for the *secondary current*, for full load, we had allowed :

$$C_1 = \frac{100\ \text{(volts)}}{2\ \text{(ohms)}} = 50 \text{ amperes.}$$

Therefore, representing 1 ampere = .03 inch, the *secondary current*, if no self-induction is present in the secondary circuit, is represented by the circle with $\overline{OC_1} = 1.5$ inch as a diameter.

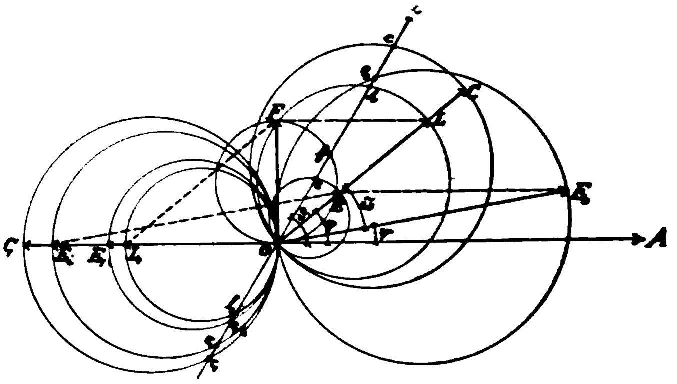

FIG. 2.

At the time, $t = \frac{T}{6}$, the secondary current is :

$$\overline{Oc_1} = -.75 \text{ inch} = -25 \text{ amperes.}$$

The M. M. F., l_1, *of the secondary current* C_1 is represented by the circle over its maximum value, $\overline{OL_1} = L_1$ as a diameter.

Now this maximum value is :

$$L_1 = n_1\, C_1 = 60 \times 50 = 3{,}000 \text{ ampere turns.}$$

1 ampere turn being chosen = .0003 inch, gives:

$$\overline{OL_1} = .9 \text{ inch.}$$

Hence, for the time, $t = \frac{T}{6}$, the instantaneous value of the secondary M. M. F. is read from the diagram to be :

$$\overline{Ol_1} = -.45 \text{ inch} = -1{,}500 \text{ ampere turns.}$$

---

[1] Usually little more than 100 ampere turns in small transformers.

[2] In the following, the *instantaneous values* of the electric or magnetic quantities will always be represented by *small letters*, their *maximum values* by *capital letters*. θ is represented by its other form in the cuts.

A METHOD FOR DETERMINING TEMPERATURE-COEFFICIENTS OF GERMAN SILVER WIRES.

BY

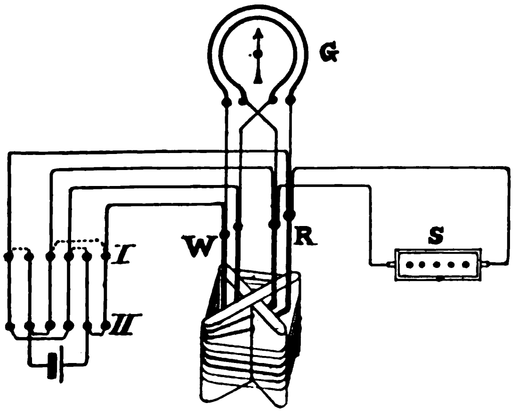
Samuel Sheldon

AND

Douglas Burnett.

CONSIDERABLE labor is required to obtain temperature-coefficients for different samples of wires for resistance coils. This could be avoided if a constant ratio between the specific conductivity and temperature-coefficient existed, as the conductivity is readily obtained. F. Kohlrausch[1] states: "It is well to mention that the temperature-coefficient can be estimated at the 10,000th part of its conductivity referred to Siemens' units." The following investigation was taken up in order to determine more definitely the ratio for German silver wires.

To obtain temperature-coefficients, a series of resistances of the wire under consideration for different temperatures is required. These were measured by the use of the "Uebergreifender Nebenschluss" (or lapped-circuit) method, the circuit for which is shown in the figure.[2]



METHOD OF DETERMINING TEMPERATURE COEFFICIENTS.

Here at W are the terminals of a standard wire, of slightly less resistance than the wire whose coefficient is to be determined. The terminals of the latter are at R. To these is shunted a rheostat, the magnitude of the resistance in which is determined by the nearness to equality of the resistances of the two wires. The equality of the currents in the two branches of the circuit, represented by the condition

$$\frac{1}{W} = \frac{1}{S} + \frac{1}{R}, \qquad (1)$$

is proved by the differential galvanometer G, the needle of which is brought to zero by adjustment of the shunt. One branch of the circuit consists of the standard wire, the other of the wire itself and its shunt.

Knowing the absolute resistance, W, of the standard, and the correct shunt resistance, S, the resistance, R, of the wire under consideration may be reduced by the formula

$$R = \frac{S\ W}{S - W} \qquad (2)$$

obtained from (1).

As the temperature of the standard and the wire changes, the shunt resistance must be changed to a large extent, compared with the change in resistance of the wire, to obtain a balance. By this means, the two resistances may be very accurately compared. Then, having a series of observations of shunt resistances, as indicated by the rheostat, of the temperatures of the rheostat coils, the standard and the wire, and knowing the absolute resistance of the standard at a definite temperature, its temperature-coefficient, the rheostat calibration-corrections, and the temperature coefficient of the rheostat coils, a series of values for the correct resistances of the wire at different temperatures is obtained by formula (2).

Let $R_{t'}$ be the resistance of the wire at a temperature t'; R_t, its resistance at a lower temperature t; R_n, its resistance at the ordinary working-temperature n; O_n, its temperature-coefficient at n; then we have:

$$\theta_n = \frac{R_{t'} - R_t}{[t' - t]\, R_n}.$$

$R_{t'}$, R_t, R_n are all obtained from the series mentioned in the last paragraph.

The temperatures which the shunt, standard, and wire had at the time of balance were obtained as follows: (1). The three temperatures, with the corresponding time as indicated on a clock-face, were observed. (2). The time at which the balance was obtained was observed. (3). The temperatures again, with the corresponding time. From plotted curves, having times as abscissæ, and temperatures as ordinates, these temperatures at the time of balance were obtained quite accurately.

Correct values for the shunt resistance for use in formula (2) were obtained by (1) taking the mean of the observed values for both sides, I. II., of the commutator; (2) applying to these the calibration-corrections; (3) applying temperature corrections.

Correct resistances of the standard, also for use in (2), were obtained by the formula

$$R_{t'} = R_t\,(1 + \theta\,[t' - t]).$$

R_t may be obtained by any of the ordinary methods. θ for the standard was obtained from a comparison of the resistances of the standard and another wire by the method just described, using the other wire as a temporary standard, having had its approximate value of θ determined from a set of measurements of its resistances at different temperatures. The two wires were here wound on separate spools, the temperature of the temporary standard remaining nearly constant, being that of the laboratory, while that of the true standard was varied.

In all other observations for coefficients the wire under consideration was doubled at the middle, as was the standard, and wound on the same spool with the standard (see figure). The measurements were made with the spool immersed in kerosene, the thermometer being beside the wires. The bath was stirred before each temperature reading. The thermometer used was graduated to tenths of a degree, readable to half-hundredths; a degree occupying about one centimetre of the scale.

Observations were made near 12°, 18°, and 22° C, the middle being the temperature of the laboratory. They were combined—low with middle, middle with high, and low with high, thus avoiding errors from temperature-lagging.

The specific conductivity of the wire, referred to Siemens' units, was then determined. The wire was removed from its spool, its length, l, in metres and its diameter in millimetres measured—the latter by micrometer calipers. Then, C, being this specific conductivity, q, its cross-section in sq. mm., we have:

$$C = \frac{1}{1.06\ R} \cdot \frac{l}{q}.$$

R was obtained from the series of resistances employed in connection with the measurement of its θ. The factor 1.06 is introduced to reduce ohms to Siemens' units.

It remained only to get the value of conductivity θ, for

---

[2] Ueber ein Verfahren, elektrische Widerstände unabhängig von Zuleitingswiderständen zu vergleichen. *Ann. Phys. u. Ch.*, xx, 1883. Here the inequalities of the galvanometer, if small, are eliminated; also the resistances of connecting wires.

the wire. These values for different wires are tabulated below. As the wires referred to in the table have different histories, as will subsequently be seen, and as the measurements were made as accurately as was deemed necessary, the mean value given is taken as the constant ratio sought. The number 8,410, reduced to have reference to ohms, becomes 8,915.

To sum up, it may be said, that, *having the resistance, R, in ohms, at a definite temperature, the length, l, in metres, and diameter, d, in millimetres, of a wire, we may get its temperature-coefficient approximate enough for ordinary use from the formula*

$$\theta = \left[\frac{l}{8915\ \pi . \left(\frac{d}{2}\right)^2 . R} \right] = \frac{l}{7{,}000\ R\ .\ d^2}.$$

The tabulated values obtained by means of this formula may be compared with those derived from actual measurement.

Wire A was drawn in 1886, and obtained from the Scovill Mfg. Co., Waterbury, Conn. It contains 25 per cent. of nickel.

Wire B was obtained from Hartmann & Braun, Frankfort a. M., Germany, and was drawn before 1886.

Wire C came from Würzburg, and was drawn before 1886.

Wire D was obtained from The E. S. Greeley & Co., of New York city. It contains 18 per cent. of nickel.

POLYTECHNIC INSTITUTE OF BROOKLYN, May 27, 1891.

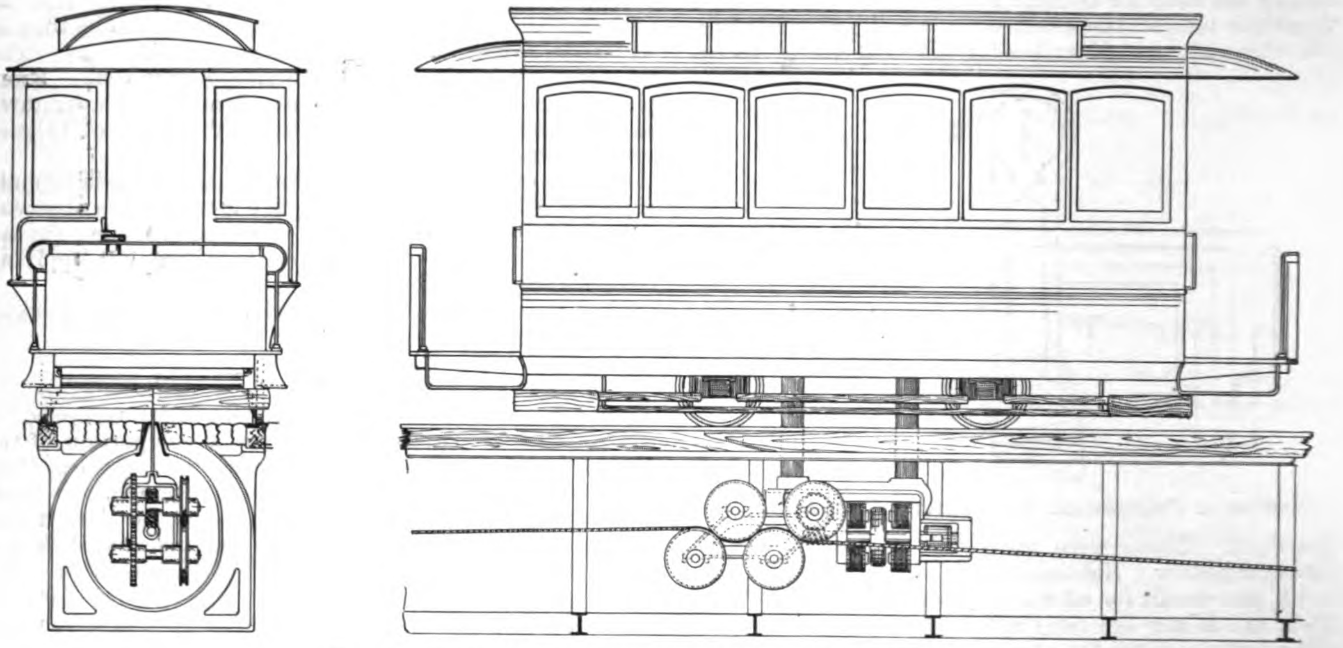
QUACKENBOSS' CONDUIT ELECTRIC RAILWAY SYSTEM.

EXTENDED experience in the operation of cable roads has shown that, despite the utmost care, the wear of the gripping devices in their tearing, grinding and crunching action on the cable, renders it necessary to replace frequently both the grips and the cable, and though a large number of devices intended to obviate this destructive effects have been tried, they do not seem to have met the want.

In seeking a way out of this evident disadvantage, Mr. P. P. Quackenboss, of this city, reasoned that a rolling contact, if it could be applied, would be less liable to damage the surface of the cable. To satisfy himself of the correctness of this assumption he experimented with a short piece of half-inch "mine" rope and ascertained the fact that it was quite unnecessary to bend it half way round a drum in order to get traction. This convinced him that if he could use the old and well-known method of making the grip roll in unison on a taut rope held between two points, he would have, as it were, a flexible rail, on which could be carried any load, according to the capacity of the rope.

The next step, that of applying the power of an electric motor, was self-evident, and as there were many objections to using this method on the surface of the ground, it necessarily had to be placed in a conduit.



FIGS. 1 AND 2.—QUACKENBOSS' SYSTEM OF ELECTRIC TRACTION.

Various considerations had led Mr. Quackenboss to the opinion that the use of the heavy equipment of the cars using the electric motor was unnecessary, as city traffic does not require express trains, but smaller cars, and more of them; these, he believes, are better able to handle traffic at less cost for installation and maintenance. To successfully carry out such a system of small car units with a motor of reduced weight evidently necessitates some method by which the power can be applied as a "dead pull," acting in the same way as the pull of horses on a car. This has been accomplished in the manner shown in the accompanying engravings, Figs. 1 and 2, which show respectively a transverse and longitudinal section of Mr. Quackenboss' railway conduit system. As will be seen, the motor, instead of driving the car directly by gearing with the wheels, is flexibly suspended and runs in a conduit, throughout the length of which a cable is laid. This cable is taken up by a "grip" arrangement consisting of a few sheaves driven by gears from the motor shaft. The slight curvature given to the cable on its passage around the sheaves is ample to afford sufficient grip, so that, when the sheaves are revolved by the motor, the car is propelled with an absolute driving power.

This fact makes the progress of the car independent of the slipping of the wheels on an icy or snow-covered track, and, on the other hand, makes the climbing of grades as easy as if the wheels geared with a rack rail.

According to Mr. Quackenboss, the wear on the cable is not one-fourth as great as by the present method of gripping, and as the cable is only slightly deflected in its passage through the sheaves (not bent round a drum as is at present the method in elevators, etc.), and as no "tension" is required, the elastic limit is not reached, and a longer life is assured. Every part of the mechanism is easily got at through the man-holes at the side of the conduit, and the inventor claims that a system of this description will make regular trips at less cost per car mile, including maintenance and repairs, than those at present in vogue.

SOME EXPERIMENTS ON THE ELECTRIC DISCHARGE IN VACUUM TUBES.[1]

BY PROF. J. J. THOMSON, M.A., F.R.S.

THE phenomena of vacuum discharges were, Prof. Thomson said, greatly simplified when their path was wholly gaseous, the complication of the dark space surrounding the negative electrode, and the stratifications so commonly observed in ordinary vacuum tubes, being absent. To produce discharges in tubes devoid of electrodes was, however, not easy to accomplish, for the only available means of producing an electromotive force in the discharge circuit was by electro-magnetic induction. Ordinary methods of producing variable induction were valueless, and recourse was had to the oscillatory discharge of a Leyden jar, which combines the two essentials of a current whose maximum value is enormous, and whose rapidity of alternation is immensely great. The discharge circuits, which may take the shape of bulbs, or of tubes bent in the form of coils, were placed in close proximity to glass tubes filled with mercury, which formed the path of the oscillatory discharge. The parts thus corresponded to the windings of an induction coil, the vacuum tubes being the secondary, and the tubes filled with mercury the primary. In such an apparatus the Leyden jar need not be large, and neither primary nor secondary need have many turns, for this would increase the self-induction of the former, and lengthen the discharge path in the latter. Increasing the self-induction of the primary reduces the E. M. F. induced in the secondary, whilst lengthening the secondary does not increase the E. M. F. per unit length. The two or three turns as shown in Fig. 1, in each, were found to be quite sufficient, and, on discharging the Leyden jar between two highly-polished knobs in the primary circuit, a plain uniform band of light was seen to pass round the secondary. An exhausted bulb, Fig. 2, containing traces of oxygen was placed within a primary spiral of three turns, and, on passing the jar discharge, a circle of light was seen within the bulb in close proximity to the primary circuit, accompanied by a purplish glow, which lasted for a second or more. On heating the bulb, the duration of the glow was greatly diminished, and it could be instantly extinguished by the presence of an electro-magnet. Another exhausted bulb, Fig. 3, surrounded by a primary spiral, was contained in a bell-jar, and when the pressure of air in the jar was about that of the atmosphere, the secondary discharge occurred in the bulb, as is ordinarily the case. On exhausting the jar, however, the luminous discharge grew fainter, and a point was reached at which no secondary discharge was visible. Further exhaustion of the jar caused the secondary discharge to appear outside of the bulb. The fact of obtaining no luminous discharge, either in the bulb or jar, the author could only explain on two suppositions, viz., that under the conditions then existing the specific inductive capacity of the gas was very great, or that a discharge could pass without being luminous. The author had also observed that the conductivity of a vacuum tube without electrodes increased as the pressure diminished, until a certain point was reached, and afterwards diminished again, thus showing that the high resistance of a nearly perfect vacuum is in no way due to the presence of the electrodes. One peculiarity of the discharges was their local nature, the rings of light being much more sharply defined than was to be expected. They were also found to be most easily produced when the chain of molecules in the discharge were all of the same kind. For example, a discharge could be easily sent through a tube many feet long, but the introduction of a small pellet of mercury in the tube stopped the discharge, although the conductivity of the mercury was much greater than that of the vacuum. In some cases he had noticed that a very fine wire placed within a tube, on the side remote from the primary circuit, would prevent a luminous discharge in that tube.

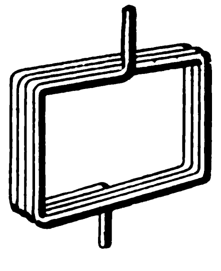


FIG. 1.

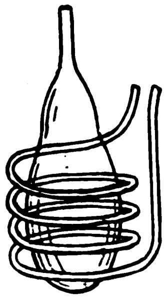

FIG. 2.

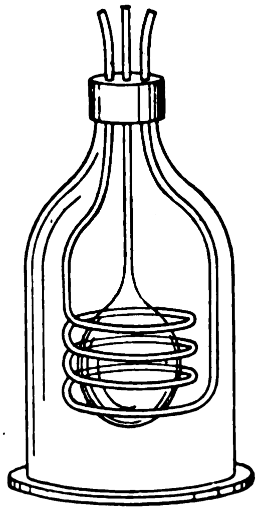

FIG. 3.

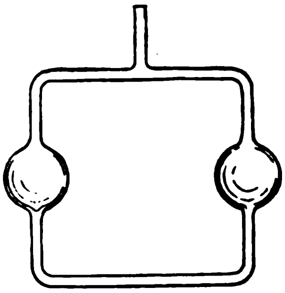

FIG. 4.

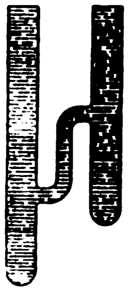
FIG. 4 shows an exhausted secondry coil of one loop containing bulbs; the discharge passed along the inner side of the bulbs, the primary coils being placed within the secondary.

SOME EXPERIMENTS ON THE VELOCITIES OF THE IONS.[1]

BY W. C. D. WHETHAM, B.A.

IN studying electrolysis, the question as to whether there is any transference of solvent when a porous wall is absent, presented itself to the author. The ordinary methods of testing for transference, such as by increase of pressure, or by overflow, not being available, when there is no diaphragm, the author used different colored solutions of the same salt, such as cobalt chloride in water and in alcohol, the former of which is red and the latter blue. By putting the solutions into a kind of U-shaped tube, any change in the position of the line of junction of the two liquids could be measured. Two aqueous solutions in which the anion was the same were also tried, one combination being cupric chloride and common salt, and in this case the line of demarcation traversed about 7 inches in three hours. The results hitherto obtained by this method agreed fairly with those found by Kohlrausch.



EXPERIMENTS ON THE VELOCITY OF IONS.

AN ELECTRICAL SNAKE STORY.

One evening, W. T. Reeves, manager of the Postal Telegraph Company, in Madison, Fla., found that his wires did not work between that point and Greenesboro. In the morning Mr. Reeves started out on an investigating tour. When within six miles of Greenesboro he found two mammoth snakes hanging across the wires in such a manner as to short circuit them. The snakes had been killed, tied together, and hung out to bring rain, the work being done by darkies in the neighborhood.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. XI. NEW YORK, JUNE 10, 1891. No. 162.

The property of the inventor is not something which his patent enables him to subtract, to self-appropriate from the world's possessions, as in the case of the old monopolies. The whole world has become, and forever after his patent has expired will continue to be, stronger or richer for the new use he has taught it to make of the powers of nature; that is the highest creation open to human power.—James J. Storrow.

ELECTRIC METERS.

MUCH has already been written and said on the subject of electric meters, and that it is still one of timely interest was made evident by the discussion called forth by the paper on electric meters read before the American Institute of Electrical Engineers, by Mr. G. W. Walker. Although it was recognized at the outset that a meter must be included in any incandescent light system making claims to commercial practicability, and although incandescent lighting has experienced a development in this country far in excess of that in any other, it is nevertheless a fact, that there are proportionally fewer meters in use among us than probably anywhere else. It is true that the causes to which this state of affairs may be ascribed are rapidly, disappearing, but they still exist to some extent and were clearly brought out in the discussion alluded to. The consumer's natural desire to have a meter which gives some visible record of the current consumed, has led to the construction of a large variety of such devices, some of which are of unquestioned value. The slowness of their adoption would therefore appear strange, were it not that a factor is here brought to bear, that unfortunately weighs heavily against the adoption of any device, however meritorious, and that is, its cost. As Prof. Thomson pointed out, there is no difficulty whatever in producing a reliable recording meter, but the fulfillment of the two conditions, reliability and cheapness, has thus far not been attended with complete success, considered from the standpoint of the average electric lighting station manager. While Prof. Thomson, in order to meet this condition of affairs, was working in the direction of obtaining a meter which could be turned out for three or four dollars, Mr. Weston pointed to the disastrous results of the past era of cheap construction, both in the station and in outside work. The inconsistency of spending large sums of money for obtaining the highest economy in the station, and then providing unreliable means of ascertaining the consumption, was too apparent to require further comment. While the theoretically perfect meter may, therefore, be still a thing of the future, it is interesting to note that the Paris meter competition has resulted in the awarding of the first prize jointly to Prof. Elihu Thomson and Prof. Aron. Considering the fact that the first report of the Testing Committee, made about a year ago, failed to determine the selection of a meter for the city of Paris municipal stations, the present results point to a striking advance in a comparatively short space of time. It is certainly most gratifying that American apparatus should have secured the prize in this manner, and Prof. Thomson is to be heartily congratulated upon his new triumph abroad. The successful apparatus is his motor meter, though not the most recent type.

IN FAVOR OF THE SINGLE TROLLEY.

As noted eleswhere in our columns, the Supreme Court of Ohio has reversed the decision of the Cincinnati Superior Court, which, on the petition of the local telephone exchange, ordered the electric street railway people to substitute the double trolley system for the single, in order to prevent induction on the telephone circuits, from the "earth return." The opinion expressed by the highest court of Ohio is, broadly, that the highway is for intercourse and traffic, and that the electric road, so far from hindering intercourse, assists it, the introduction of the single trolley system, with the incidental use of the earth return, being but a further and legitimate extension of the principle upon which all street railway franchises are granted. This is, indeed, the broad, real issue, and it has always seemed doubtful that, even if telephonic troubles were unabatable by remedies, the electric railway would be banished from our streets because it interfered with the telephonic conversations of perhaps 5,000 people out of a population of 500,000, upon everyone of whom the electric roads were conferring a benefit, by giving in its best form the very service for which roads and highways are constructed. The objections on the score of troubling the telephone have been paralleled by those from some of the Eastern towns where the overhead trolley wires have been found to interfere quite materially with the success of circus parades. It is true that both telephones and circuses were here before electric street railways, and to that extent are entitled to consideration; but if it were a question of preserving just that which did the most good to the community, in its use of the thoroughfares, or of the earth, we think that the electric road would be the last thing to be abandoned.

But the situation has never reached that extremity nor is it likely to do so. We believe that this decisi on will be stimulative to ingenuity in devising means to deprive induction of its effects on telephone circuits. Even if it did not, it will help forward the more general use of metallic telephone circuits, in the resort to which a practical and effective cure is most assuredly found.

ELECTRICITY AT THE WORLD'S FAIR.

The Frankfort Electrical Exhibition has now begun to assume good shape, and promises to be both interesting and successful. It would not be a bad thing if Prof. Barrett and Mr. F. Sargent, to whom the electrical work at the Chicago World's Fair has now been committed, could run over to Europe this summer and see for themselves what has been done at Frankfort and note the chief novelties or lines of development. We believe that a month could be spent to advantage in this way, for no matter how much may be learned from reports on such a subject, actual observation is much to be preferred.

Matters electrical of the World's Columbian Exposition are progressing very satisfactorily, and work has now begun in earnest. The appointment of an electrical engineer attached to the Department of Electricity as assistant to Prof. J. P. Barrett, to work out the detail portions of the Professor's ideas and see that they are carried out, will shortly be made, but at the date of writing this appointment has not yet been definitely settled. Prof. Barrett's plans will then be turned over to Mr. Frederick Sargent, the electrical engineer of the Construction Department, to carry out in accordance with their requirements as regards erection and construction, and Prof. Barrett's assistant will also act under the instructions of Mr. Sargent as far as the latter may require his services.

THE FUTURE OF THE ALUMINUM PROBLEM.

The question whether the aluminum of the future will be produced by chemical or electrical methods is of the utmost importance, regarded scientifically, and has an important bearing when viewed from the commercial standpoint. As Dr. Wahl pointed out in his admirable paper read before the American Institute of Electrical Engineers, chemists have been spurred on by the success attained by the electrical engineer, in extracting the metal by the aid of the heat produced in electric furnaces, in connection with electrolytic action, and it is fair to assume that they will not give up the struggle without a serious attempt at recovering the lost ground. But Dr. Wahl also gave sufficient data to show that even in its present state the electrical method of aluminum extraction was more than able to withstand the competition of the purely metallurgical methods. While we have no fear, therefore, for the future of the electrical aluminum processes, we believe that improvements are necessary in order to bring this metal to the position which it ought to occupy in the arts. Complaints have from time to time been heard against aluminum, which, without doubt, can be traced directly to the fact that the metal operated with was not pure, and hence did not give the results which a better product would have furnished. A small percentage of impurities has a very large influence on the character of the metal and of the alloys of which it forms a part, and as the metal will probably be used more in the form of an alloy, it becomes of the greatest importance to so improve the processes of manufacture that complaints, on the score above mentioned, may no longer be heard.

CONSTANT CURRENT AND CONSTANT POTENTIAL TRANSFORMERS.

Although the constant current transformer has found but very little application at the present day in comparison with that of the constant potential type, it is well to bear in mind the conditions which govern these two types of converters. Thus, as Mr. Steinmetz points out elsewhere, in the constant potential transformer the magnetization, and therefore the iron loss, is a constant quantity, no matter what the load at which the transformer is operating, while the loss in the copper, of course, varies, as the square of the current. In the constant current transformer, however, the reverse is the case, the loss in the copper here being a constant quantity, while that in the iron varies with the load in the proportion of 1.7 power of the magnetization. In predetermining the efficiency of a system it would therefore be well to take into account the differences here pointed out, as under certain conditions of operation the series system might be found more economical than the constant potential.

The Quackenboss Traction System.

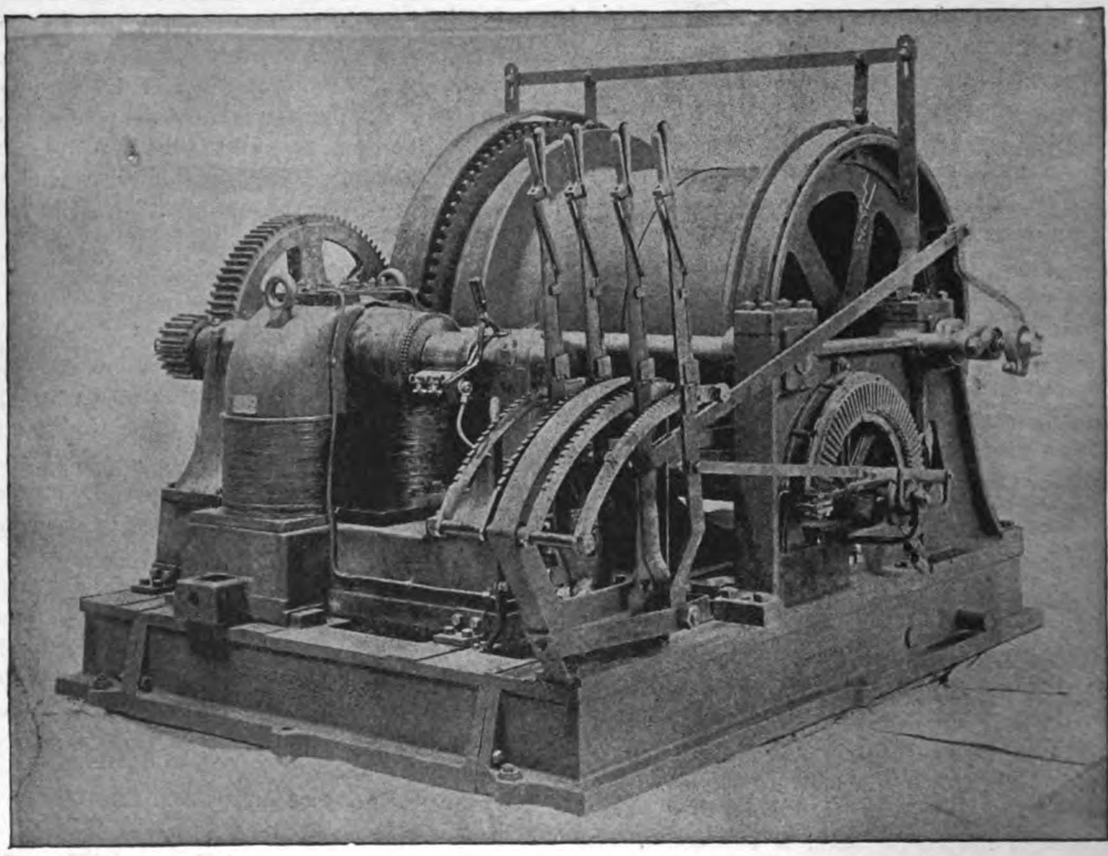
Of the various systems proposed for the application of electricity to tractive purposes, there are probably none which have afforded the car what might be called a "dead pull," with the exception, perhaps, of one or two isolated cases in which a rack rail is employed. The advantage which such a system possesses, especially on roads embodying heavy grades, is too obvious to need pointing out, and our readers will therefore be interested in the very ingenious device due to Mr. P. P. Quackenboss, and described on another page. It will be noted that the inventor obtains a direct pull for the propulsion of the car by driving a set of sheaves gripping a cable placed in a conduit, instead of applying the power to the car axles, as has heretofore been the case. The idea is one which is certainly worthy of further consideration.

A Chicago-Milwaukee Electric Road.

A scheme is on foot to build an elevated railway between Chicago and Milwaukee to be operated by electricity, in which it is stated a number of Baltimore capitalists, who have recently made a visit to Milwaukee, will be interested. It is proposed to organize a stock company of Eastern, Chicago, and Milwaukee capitalists with sufficient capital to build a direct road operated by electricity with double track between Chicago and Milwaukee, to be in operation by the opening of the World's Fair. This project, if carried out, will be watched with great interest as the first substitution of the electric locomotive for the steam engine on so large a scale, and over so large a run. It is to be hoped that such a scheme will not be entered upon without full consideration of its many important points, but, though it was expected that the more thickly settled East would see the first attempt at high speed electric traction, after all it may be that the newer conditions of the West are the more inviting.

A THOMSON-VAN DEPOELE MINE HOIST IN THE WEST.

AMONG the many advantages of the electric system of haulage for underground work is the ease with which the locomotive may be helped out, so to speak, where an incline occurs in the haulage way, by means of stationary electric hoists operated on the same circuit with the locomotive, and by their use making possible the employment of much smaller locomotives than would be possible otherwise. For instance, for certain haulage work in a coal mine, a 40 h. p. locomotive is necessary. As the entry is driven forward a fault is met in the measure, and the grade for a comparatively short distance is so increased that the locomotive, already in, will be unable to handle the work. An auxiliary stationary hoist set up at the top of this hill will remedy the difficulty. For this work special apparatus is necessary, and the Thomson-Van Depoele Electric Mining Co. has gotten out electric hoists particularly for underground haulage plants. The illustration shows one of these as recently made for a Western coal mine. The plant originally consisted of one hoist, but its work and the results obtained by its use proved so eminently satisfactory that two other hoists were immediately ordered.



THOMSON-VAN DEPOELE MINE HOIST.

The outside dimensions of the hoist are 9′ by 7′ 4″, and the total height is nearly 6′. The motive power is furnished by a Thomson-Houston motor of 35 h. p., and wound for a potential of 440 volts. It is series wound and runs normally under load at a speed of 1,100 revolutions per minute. A speed reduction from the motor armature to the drum of 25½ is accomplished by one intermediate shaft with proper gears and pinions. This gives a rope speed of a little over 500 foot per minute or 0.492 foot per revolution of the motor. The drum, which is mounted on a sleeve and is thrown into action with the large gear by a friction clutch, is four feet in diameter with a 36″ face. Its rotation, when running independently is governed by two band brakes which extend around nearly the entire circumference of the drum. The outfit is equipped with five controlling levers, four of which are shown in the illustration. One operates the rheostat contact, one the drum clutch, two are brake levers, which are entirely independent one from the other, and the last throws the reversing switch, giving the drum, when thrown into action with the motor, positive motion in either direction of rotation. The controling levers are all latched, and all within easy reach of the operator. The gears and pinions are noiseless and carefully covered to prevent accidents, and the motor has self-oiling bearings. The Thomson-Van Depoele Electric Mining Co. is getting out hoists of this general description in varying sizes and for different capacities, and will furnish estimates and information upon application.

OPENING OF THE FRANKFORT EXHIBITION.

Saturday, May 15th, witnessed the opening of the electrical exhibit at Frankfort-on-the-Main, under very favorable circumstances. A brief description of the principal features, although necessarily incomplete, may be of interest at this stage of the work. The boiler house, lying directly back of Machinery Hall, contains 21 boilers, of which 20 are now ready for actual service. These present a heating surface of more than 27,500 square feet.

In Machinery Hall there are more that 60 prime motors, many of which are already in use. Many of the dynamos are coupled directly to the engines, especially where both have been manufactured by the same firm.

Messrs. Siemens and Halske have in charge the erection of the central station, and their installation will shortly be complete.

Schuckert & Co., of Nuremberg, exhibit several steam engines and a number of dynamos and motors, and have undertaken to light a portion of the exhibition. The Thomson-Houston Co., of Hamburg, show two dynamos and an electro-magnet capable of sustaining a weight of one ton, intended for transporting iron castings in foundries.

The Helios Co., of Cologne, have a 600 h. p. steam engine by Panckseh, coupled to a 2,000 volt, 400 kilowatt alternator. This machine will deliver 30,000 watts for lighting the Palm Gardens at the other end of the town. Various other machines are also included in their display.

The entire output of the dynamos is estimated at 3,950 h. p. About 30 firms exhibit dynamos, motors, and transformers, while 20 show steam engines, and 12 gas engines. The transmission of 300 h. p. from Lauffen-on-the-Neckar has been delayed, and will probably not be accomplished before August 15.

The department for the distribution of electricity will exhibit transformers of all kinds, pressure regulators, automatic rheostats, etc. On either side of this building are workshops, the power for which is derived from Machinery Hall. The technical arrangements for these are in charge of engineers Sarasin and Stahl, who have some 35 motors of various types, ranging from $\frac{1}{16}$th to 25 h. p. at work.

Finally, on the left of Machinery Hall is an artificial mountain, under which is a model mine with an underground electric railway and electric boring machines, and over which flows a cascade lighted from below with electric light.

Reports of Companies.

MEXICAN TELEPHONE CO.

Treasurer W. French Smith reports for the year ended Feb. 28, 1891:

Cash Feb. 28, 1890	$5,273.86
Receipts in Mexico	76,068.79
Receipts in Boston	18,460.06
Total	$99,802.71
Increase for the year	21,909.16
Payments in Mexico	60,150.86
Payments in Boston	26,560.78
Cash on hand, Boston	12,100.19
Cash on hand, Mexico	990.89
Total	$99,802.71
Increase for year	18,071.30
Less extraordinary expenses	14,800.00
Making the normal increase	$3,271.30
Receipts in Boston, including a cash balance of $4257.16	38,660 97
Payments in Boston	26,560.78
Balance Feb. 28, 1891	$12,100.19

	1890-91.	1889-90.	Inc.
Telephones in service	1.123	1,045	78
Rentals for the year	$66,782	$54,773	$12,008
Gross earnings in Mexico	76,068	65,780	10,288
Operating in Mexico	41,818	41,301	516
Net receipts	12,504	16,522	......

WESTINGHOUSE AFFAIRS.

With regard to the further postponement of the Westinghouse annual meeting until June 23, and the progress of the scheme for reorganization, Mr. Bannister, the vice-president of the Westinghouse Electric Co., says:—"Mr. Westinghouse tells me that all that is necessary for the complete success of the reorganization plan is that the stockholders should come in at once and exchange their stock for the receipts of the Mercantile Trust Company. He says that he is meeting with very gratifying success, and that already more than half the total number of shares have been so deposited. Forty per cent. of the stock so released will be used to pay off a charge of $250,000, and this in itself will be a great relief. If the remaining stockholders will only send in their stock at once to the Mercantile Company, the meeting of June 23 will see the reorganization perfected and the company placed in a position which will enable it to do a bigger business than ever."

Society and Club Notes.

MEETING OF THE EXECUTIVE COMMITTEE OF THE NATIONAL ELECTRIC LIGHT ASSOCIATION.

A meeting of the Executive Committee of the National Electric Light Association is to be held at Montreal, Canada, on the 8th inst., to arrange details for the coming convention.

An unusually active interest is being taken this year in the Montreal meeting, and it looks very much as though the attendance and objects of interest displayed will equal, and even exceed, those of former conventions. The popularity of this Association has been growing with remarkable vigor during the past few years until now the strength of the organization places it on a plane with the great societies, not only of this country, but of the world. This is deservedly so, owing to the very practical nature of its objects and labors, and the aid it affords to its members in a knowledge of the most economical and efficient solutions of the every day problems arising in the course of commercial work.

The immense Victoria Skating Rink at Montreal will be used for the purposes of the exhibition, as it has been found that a smaller hall would not be sufficiently large to accommodate the many who are anxious to obtain space.

THE ELECTRIC CLUB.

At the meeting of the Board of the Electric Club on June 4, there were admitted 33 new members—1 life, 6 active and 26 associate, showing that the late rapid rate of growth is being well maintained. About a dozen new applications already await the attention of the Membership Committee. The report of the treasurer showed that the finances of the club are in progressively healthy condition. From the statement of the House Committee it appears likely that should the lease by the club of its present quarters be extended a couple of years, as proposed, the sleeping accomodations will be increased, as there is a brisk demand for rooms all the time.

It has been arranged to have the smoking concert on the third Thursday of this month, June 18th, and the Entertainment Committee report that an excellent programme is now secured, with the probability of the addition of other talented performers from the electrical ranks. The concert will be preceded by a business meeting of the club.

Letters to the Editor.

OIL AS AN INSULATOR FOR HIGH TENSION CIRCUITS.

In your issue of May 13, page 540, there appeared an article signed by Mr. David Brooks, in which he quotes me as follows: "For conveying extremely high tension current, only the overhead system can be practically considered, and it is possible to construct an overhead line in such a manner that even with the highest voltage there will be practically no leakage."

I beg to remark that this is inaccurate and I should think that Mr. Brooks has seen a bad translation of my paper read in Frankfort, which was reproduced in the *Elektrotechnische Zeitschrift*, and by referring to which he will see that the above alleged statement is wrong. I have never stated that the overhead system only, could be practically used for currents of very high tension, but as the paper was especially read in the interest of the Frankfort-Lauffen installation, I suggested that in this particular case another way of transmitting the power over so long a distance would not be practical.

Mr. Brooks will undoubtedly admit that it is most important to find out the maximum tension at which an overhead line with naked wire on good insulators can be worked without considerable leakage, as economy in the line is always a point of first consideration.

The experiment to be carried out at the Frankfort exhibition will no doubt give us the desired information.

In conclusion, I must now inform you that I do not consider air a very good insulator, since my transformers for high tension are immersed in oil, which fact proves that our ideas on insulation are not opposed.

C. E. L. Brown.

Oerlikon bei Zurich, May 23, 1891.

Patent Notes.

ELECTRIC RIVETTING INTERFERENCES.—THOMSON vs. RIES.

With regard to the recent alleged victory of Ries over Thomson on electric rivetting, Mr. H. N. Sweet, of the Thomson Electric Welding Co., writes us that the reports are somewhat misleading. "The decision referred to," he says, "was that of the lowest tribunal in the Patent office, from whose conclusions there are two appeals. We believe the decisions of the Examiner of Interferences are wrong, and an appeal has already been taken and argued. This interference relates merely to a refinement of the inventions of Prof. Thomson already patented to him in patents which cover broadly the subject matter of the interference which is referred to. No electric rivetting can by any possibility be done without infringing patents already issued to Prof. Thomson, as a reference to those patents will show." We are informed (June 8), that an appeal to the Board of Examiners in chief has just been decided in Prof. Thomson's favor.

Appointments, Etc.

Mr. W. H. Cull has been appointed electrician of the Hudson River Telephone Co., of Albany, N. Y. He will give his immediate attention to the reorganization also of the messenger service.

Mr. E. Haston has become electrician and engineer at the Great Barrington, Mass., central station.

Mr. J. D. Bishop has become connected with John A. Roebling's Sons Co. as electrical engineer in their electrical department.

Mr. George E. Hanson, who established the Somerville service of the New England Telephone Co., has been transferred to the Boston office of the company to discharge new and more important duties.

Mr. Redington Fiske is to have charge of the Western division of the Boston surburban telephone service, with headquarters in Brookline.

Mr. I. O Wright is to have charge of the Eastern division of the Boston suburban telephone service, with headquarters at Somerville.

Mr. Carter, of the Thomson-Houston Co., has been engaged as electrician by Henry Newhall & Co., of Danvers, Mass.

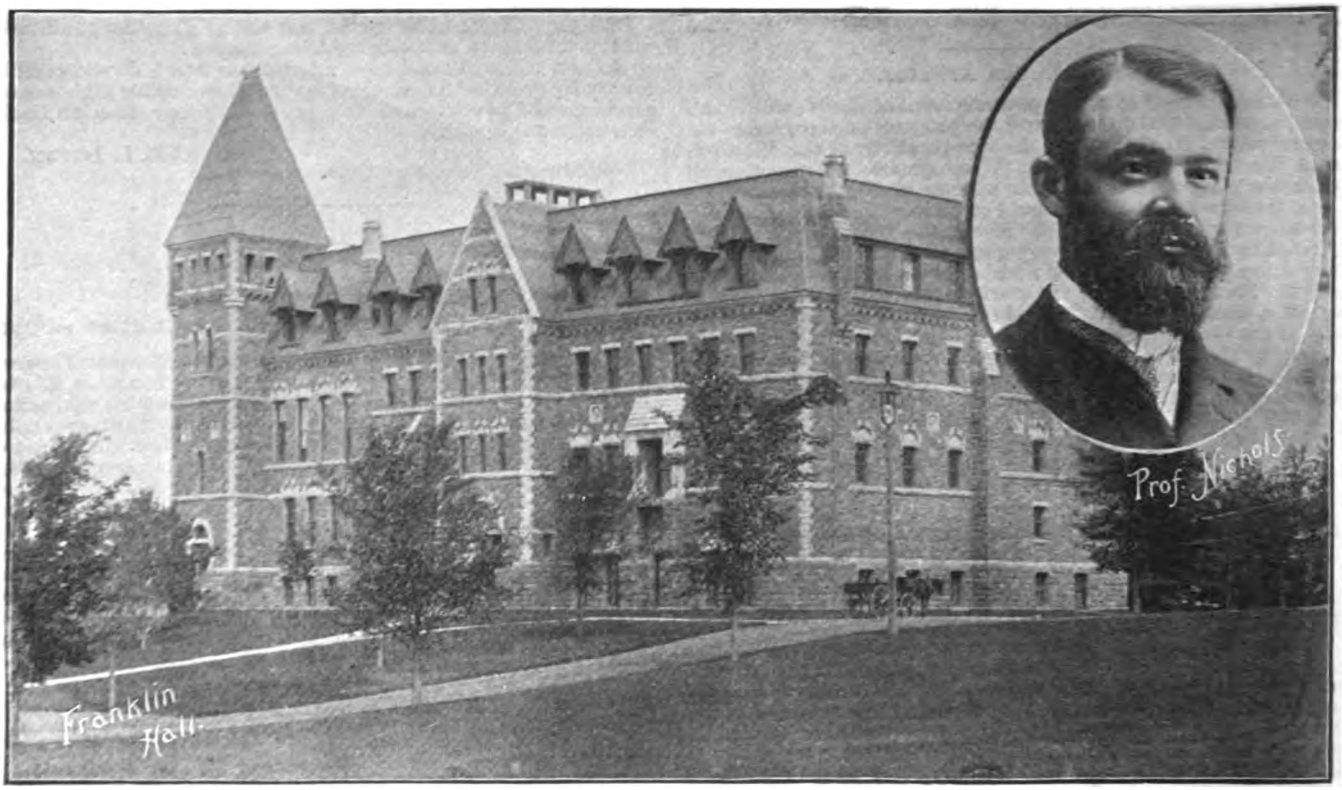
Mr. Eben Nevins, who has been chief engineer and electrician at the Plymouth, Mass., Electric Light Co.'s station, has taken charge of the power plant of the electric street railway at Newburyport.

College Notes.

CORNELL UNIVERSITY ELECTRICAL ENGINEERING DEPARTMENT.

The building exclusively occupied by the Department of Physics is called Franklin Hall, "in honor of the first American electrician," whose head in terra-cotta bas-relief adorns the doorway.

At the time of its erection in 1888, Franklin Hall, which was designed as a physical and chemical laboratory combined, was deemed ample for the accommodation of both departments. At the present time, however, the entire building is given over to the study of experimental physics. On the first floor is the large lecture room especially equipped for demonstrations. It is here that the student begins his acquaintance with the science which, if he be an engineer, will occupy more or less of his time during three years of his college course. Besides other recitation rooms, the cabinet of apparatus, occupying three large rooms adjoining the lecture room, and the laboratories for practice work in general physics, applied electricity, photometry, and practical photography, Franklin Hall contains many rooms where original investigation can be carried on. Research, indeed, is regarded as a very important feature of the work of the department, and it forms an essential element in the training of all advanced students in physics. Such students come to it well equipped after a year of lectures and recitations, a year in the junior laboratories, and a year of more difficult work in heat and applied electricity. At the head of the department is Professor E. L. Nichols.



FRANKLIN HALL, CORNELL UNIVERSITY, ITHACA, N. Y.

The dynamos that are used for University lighting, shown on p. 659, are arranged to be operated with the greatest economy and satisfaction, as well as to afford opportunity for complete "plant" testing by students of electrical engineering. They have been placed in the steam-engine laboratory in the closest proximity to the sources of water and steam power. For the incandescent lighting of shops, laboratories, and offices, current is obtained from an Edison 500 light dynamo, a gift to the University by Mr. Edison. Arc lamps in shops and armory and on the campus, are supplied with current from a 40-arc light alternator, presented to the University by the Westinghouse Electric Company.

The dynamos are so installed that they may be driven by water or steam power, or both. Ordinarily they are operated by water power, furnished by the turbine water wheel in the Ithaca Gorge, and are driven from the shop main-line shaft by belting through a jack-shaft. This connection to the line shaft is made automatically when the machines are to be started, so that the line shaft does not have to be stopped. The jack-shaft is equipped with friction-clutch pulleys of the most approved make, enabling each machine to be started and stopped independently.

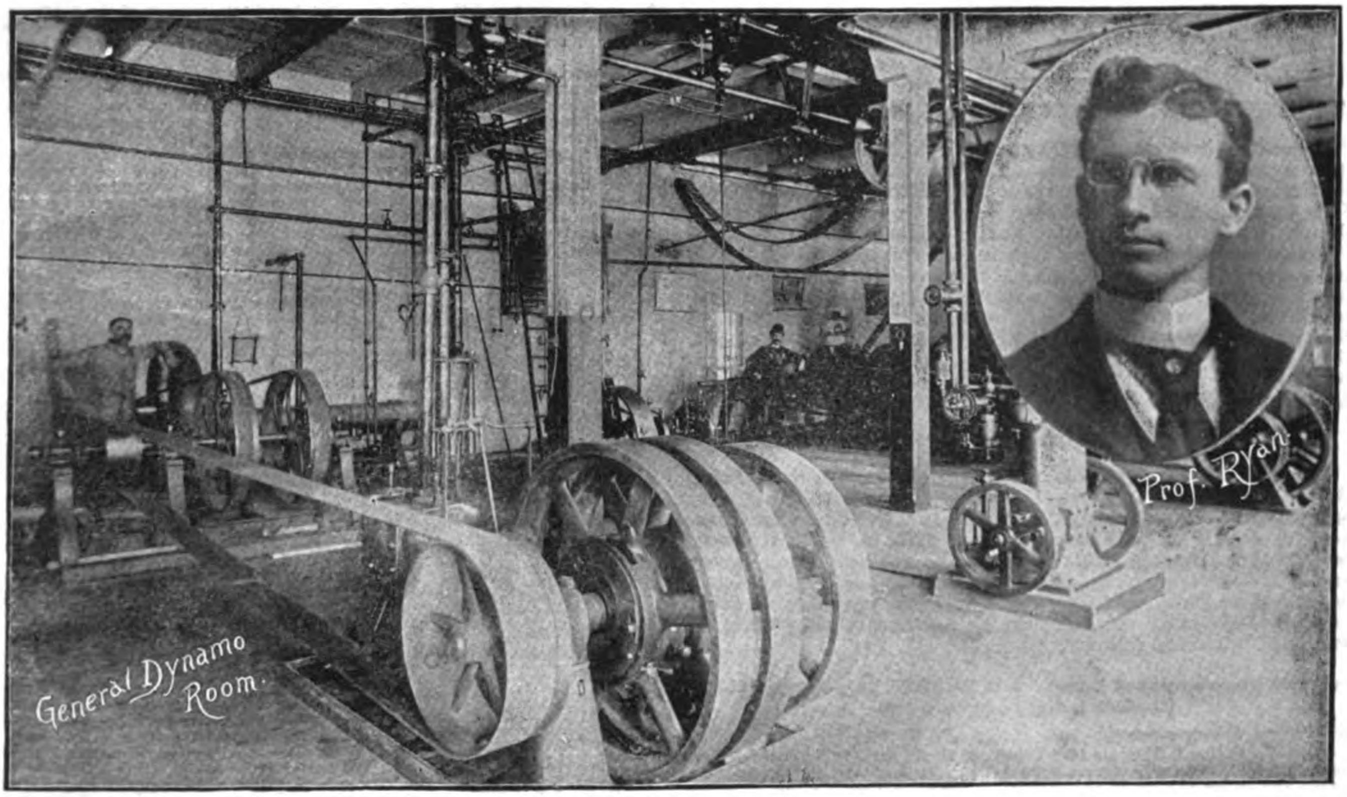
A Straight-Line automatic engine is so arranged that it can be belted to the jack-shaft at any time without stopping, and is thus used ordinarily to help the water-power over the maximum demand for power in the shops, and for lights, that occurs between five and six o'clock. The dynamo room is in charge of Professor H. J. Ryan.

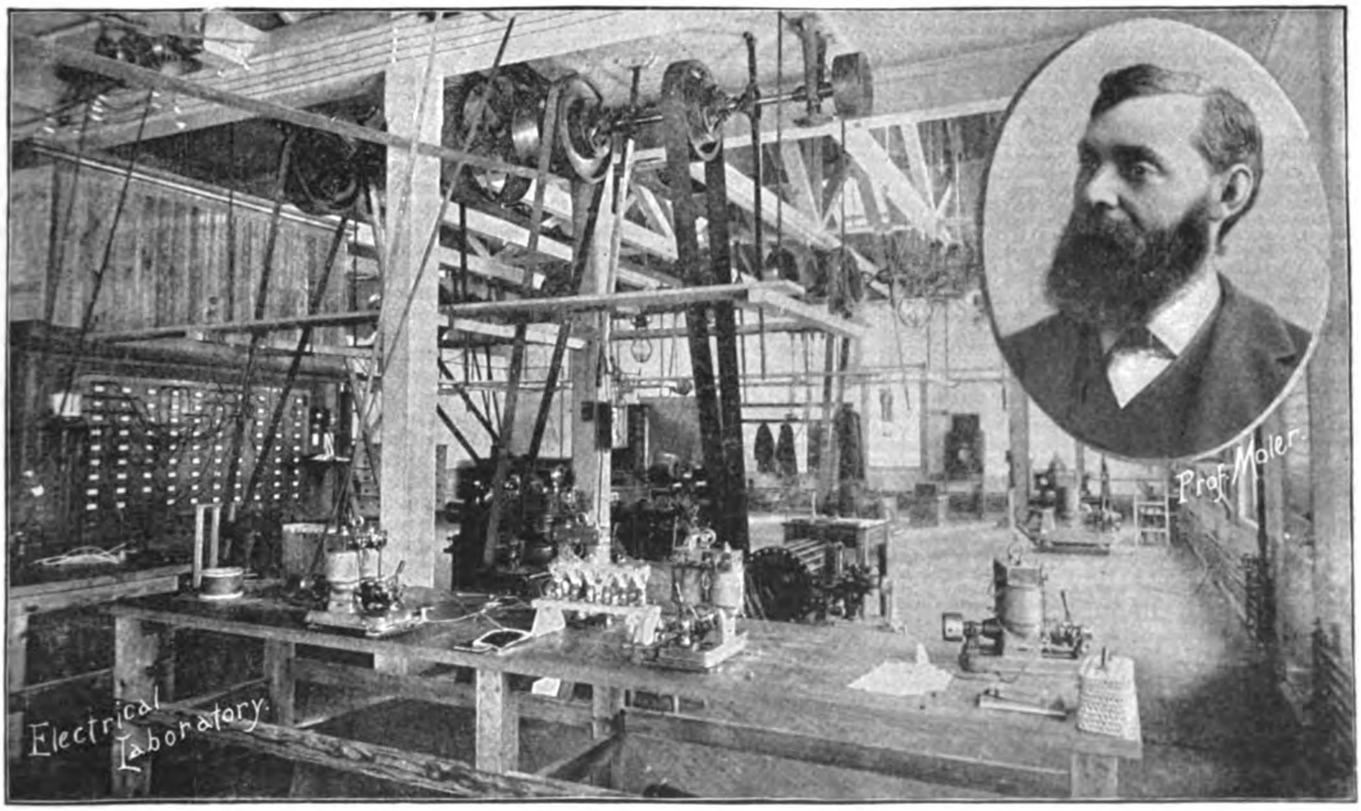
The Dynamo Laboratory, of which a view is shown on the opposite page, is believed to be the largest college dynamo room in this country, if not in the world. It contains no machines that are used in regular lighting service, but is devoted entirely to the experimental study of dynamos and motors The floor space is 40 x 70 feet; there are three lines of main shafting overhead that are driven by steam and water power. The collection of dynamos includes nearly all the well-known commercial types, together with many machines of unusual form, constructed especially for experimental purposes. These machines are of various sizes, from 20 h. p. down, and they are arranged with special reference to the requirements of experimental work.

An important part of the work in applied electricity, the measurement of currents and electromotive forces, together with a detailed study of storage batteries, arc lamps, voltmeters and electric meters, is carried on in the annex to Franklin Hall, which is a substantial one-story building 100 x 87 feet. Operations of extreme precision are conducted in the Magnetic Observatory, an isolated building entirely free from iron, which contains the great galvanometer and other standard instruments for measuring current and potential, and the magnetic elements. Professor G. S. Moler is in charge of this laboratory.

NEW ELECTRICAL WORK AT OIL CITY, PA.

The fact that a large electric light plant has just been installed at Oil City, Pa., in the very heart of the great oil region, deserves more than passing mention. The station of the local company is 94 feet by 57, and is built of brick with an iron bridge roof. The plant consists of four 60 arc light Western Electric machines, and one 1,000 light National alternating current machine. These dynamos are run from a line of shafting with Hill clutches, belted to two 260 h. p. four valve engines from Russell, of Massillon, O. The fly-wheels of engines are 10 feet in diameter with 36 inch face, and the pulleys on shafting are 46 inches in diameter with 36 inch face. The belts were furnished by the Munson Belting Co., of Chicago. There are two batteries of boilers made by the Oil City Boiler Works. A contract has been obtained from the city to light the streets for ten years with 91 lamps at $80 per lamp of 2,000 c. p., and it is expected to increase this to 125 lamps. This fine plant is being installed by Mr. T. L. Paulson, of the Western Electric Co., and is to be running about June 15. A charter has also been secured by another new local company for





DYNAMO ROOM AND ELECTRICAL LABORATORY, CORNELL UNIVERSITY, ITHACA, N. Y.

an electric railway. Mr. J. B. Smithson is one of the leading spirits of the enterprise. It is said that the road will soon be put in, but the system has not been selected as yet.

ELECTRICAL PROGRESS IN JAPAN.

The Tokio Electrical Society has appointed a committee of 15 to make investigations and publish rules and regulations as standard requirements for electrical installations. The telephone exchange of Tokio City, Japan, in charge of the government, is reported as very prosperous. The present number of subscribers is 320, while the population is 1,207,022, and the total number of houses 277,049. The Yokohama exchange has 70 subscribers. Nearly all the telegraph and post offices have been combined, and are now in a prosperous condition. An electric elevator is running every day at Tokio, in a tower. The current is supplied by the Tokio Electric Light Company. The motor used is a 10 h. p. Sprague. Experimental works are carried on at two or three different places in the Japanese Empire for refining copper by electricity.

Legal Notes.

THE EDISON INCANDESCENT LAMP LITIGATION.—I.

The action brought in 1885 by the Edison Electric Light Company against the United States Electric Lighting Company, in the United States Circuit Court for the Southern District of New York, came up for final hearing before Hon. W. J. Wallace, Circuit Judge, on May 25th. Eaton & Lewis, solicitors for the complainant company, were represented by Richard N. Dyer, Grosvenor P. Lowrey, Clarence A. Seward and Sherburne Blake Eaton, of counsel. Messrs. Duncan, Curtis & Page, solicitors for the defendant, were represented by Samuel A. Duncan, Edward Wetmore, Leonard E. Curtis, and Frederick H. Betts, of counsel. The preliminaries having been arranged, the hearing was adjourned to May 26th, at 11 o'clock, at which time the opening argument in behalf of the complainant was begun by Richard N. Dyer.

ARGUMENT OF MR. DYER FOR THE EDISON COMPANY.

Mr. Dyer said that this was a suit of the Edison Electric Light Company against the United States Electric Lighting Company, upon a patent of Thomas A. Edison for an improvement on electric lamps, granted January 27th, 1880, which patent, the complainant contended, covered the modern incandescent lamp with which we have of late years become familiar as a means of household lighting. Mr. Dyer then handed to the court a model of the lamp described in the patent, which latter he proceeded to read as follows:

Specification forming part of Letters Patent No. 223,898, dated January 27, 1880.
Application filed November 4, 1879.

***To all whom it may concern*:**

Be it known that I, Thomas Alva Edison, of Menlo Park, in the State of New Jersey, United States of America, have invented an Improvement in Electric Lamps, and in the method of manufacturing the same (Case No. 186), of which the following is a specification:

The object of this invention is to produce electric lamps giving light by incandescence, which lamps shall have high resistance, so as to allow of the practical subdivision of the electric light. The invention consists in a light-giving body of carbon wire or sheets coiled or arranged in such a manner as to offer great resistance to the passage of the electric current, and at the same time present but a slight surface from which radiation can take place.

The invention further consists in placing such burner of great resistance in a nearly perfect vacuum, to prevent oxidation and injury to the conductor by the atmosphere. The current is conducted into the vacuum-bulb through platina wires sealed into the glass.

The invention further consists in the method of manufacturing carbon conductors of high resistance, so as to be suitable for giving light by incandescence, and in the manner of securing perfect contact between the metallic conductors or leading-wires and the carbon conductor.

Heretofore light by incandescence has been obtained from rods of carbon of 1 to 4 ohms resistance, placed in closed vessels, in which the atmospheric air has been replaced by gases that do not combine chemically with the carbon. The vessel holding the burner has been composed of glass cemented to a metallic base. The connection between the leading-wires and the carbon has been obtained by clamping the carbon to the metal. The leading wires have always been large, so that their resistance shall be many times less than the burner, and in general, the attempts of previous persons have been to reduce the resistance of the carbon rod. The disadvantages of following this practice are, that a lamp having but 1 to 4 ohms resistance cannot be worked in great numbers in multiple arc without the employment of main conductors of enormous dimensions; that, owing to the low resistance of the lamp, the leading-wires must be of large dimensions and good conductors, and a glass globe cannot be kept tight at the place where the wires pass in and are cemented; hence the carbon is consumed, because there must be almost a perfect vacuum to render the carbon stable, especially when such carbon is small in mass and high in electrical resistance.

The use of a gas in the receiver at the atmospheric pressure, although not attacking the carbon, serves to destroy it in time by "air-washing," or the attrition produced by the rapid passage of the air over the slightly coherent highly-heated surface of the carbon. I have reversed this practice. I have discovered that even a cotton thread properly carbonized and placed in a sealed glass bulb exhausted to one-millionth of an atmosphere offers from 100 to 500 ohms resistance to the passage of the current, and that it is absolutely stable at very high temperatures; that if the thread be coiled as a spiral and carbonized, or if any fibrous vegetable substance which will leave a carbon residue after heating in a closed chamber be so coiled, as much as 2,000 ohms resistance may be obtained without presenting a radiating-surface greater than three-sixteenths of an inch; that if such fibrous material be rubbed with a plastic composed of lamp-black and tar, its resistance may be made high or low, according to the amount of lamp-black placed upon it; that carbon filaments may be made by a combination of tar and lamp-black, the latter being previously ignited in a closed crucible for several hours and afterward moistened and kneaded until it assumes the consistency of thick putty. Small pieces of this material may be rolled out in the form of wire as small as seventy-one thousandths of an inch in diameter and over a foot in length, and the same may be coated with a non-conducting non-carbonizing substance and wound on a bobbin, or as a spiral, and the tar carbonized in a closed chamber by subjecting it to high heat, the spiral after carbonization retaining its form.

All these forms are fragile and cannot be clamped to the leading-wires with sufficient force to insure good contact and prevent heating. I have discovered that if platinum wires are used and the plastic lamp-black and tar material be molded around it in the act of carbonization there is an intimate union by combination and by pressure between the carbon and platina, and nearly perfect contact is obtained without the necessity of clamps; hence the burner and the leading-wires are connected to the carbon ready to be placed in the vacuum-bulb.

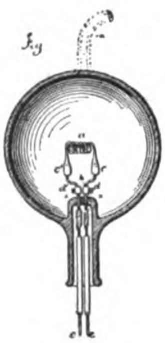
When fibrous material is used the plastic lamp-black and tar are used to secure it to the platina before carbonizing.

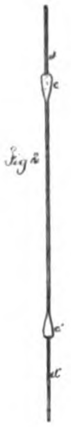
By using the carbon wire of such high resistance I am enabled to use fine platinum wires for leading-wires, as they will have a small resistance compared to the burner, and hence will not heat and crack the sealed vacuum-bulb. Platina can only be used, as its expansion is nearly the same as that of glass.

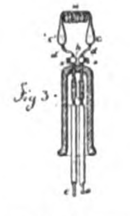
By using a considerable length of carbon wire and coiling it, the exterior, which is only a small portion of its entire surface, will form the principal radiating-surface; hence I am able to raise the specific heat of the whole of the carbon, and thus prevent the rapid reception and disappearance of the light, which on a plain wire is prejudicial, as it shows the least unsteadiness of the current by the flickering of the light; but if the current is steady the defect does not show.

I have carbonized and used cotton and linen thread, wood splints, papers coiled in various ways, also lamp-black, plumbago, and carbon in various forms, mixed with tar and kneaded so that the same may be rolled out into wires of various lengths and diameters. Each wire, however, is to be uniform in size throughout.

If the carbon thread is liable to be distorted during carbonization it is to be coiled between a helix of copper wire. The ends of the carbon or filament are secured to the platina leading-wires by plastic carbonizable material, and the whole placed in the carbonizing chamber. The copper, which has served to prevent distortion of the carbon thread, is afterward eaten away by nitric acid, and the spiral soaked in water, and then dried and placed on the glass holder, and a glass bulb blown over the whole, with a leading-tube for exhaustion by a mercury-pump. This tube, when a high vacuum has been reached, is hermetically sealed.







With substances which are not greatly distorted in carbonizing, they may be coated with a non-conducting non-carbonizable substance, which allows one coil or turn of the carbon to rest upon and be supported by the other.

In the drawings, figure 1 shows the lamp sectionally. *a* is the carbon spiral or thread. *c c'* the thickened ends of the spiral, formed of the plastic compound of lamp-black and tar. *d d'* are the platina wires. *h h* are the clamps which serve to connect the platina wires, cemented in the carbon, with the leading-wires *x x* sealed in the glass vacuum-bulb. *e e* are copper wires, connected just outside the bulb to the wires *x x*. *m* is the tube (shown by dotted lines) leading to the vacuum pump, which, after exhaustion, is hermetically sealed and the surplus removed.

Figure 2 represents the plastic material before being wound into a spiral.

Figure 3 shows the spiral after carbonization, ready to have a bulb blown over it.

I claim as my invention:

1. An electric lamp for giving light by incandescence, consisting of a filament of carbon of high resistance, made as described, and secured to metallic wires, as set forth.

2. The combination of carbon filaments with a receiver made entirely of glass and conductors passing through the glass, and from which receiver the air is exhausted, for the purposes set forth.

3. A carbon filament or strip coiled or connected to electric conductors so that only a portion of the surface of such carbon conductors shall be exposed for radiating light, as set forth.

4. The method herein described of securing the platina contact-wires to the carbon filament and carbonizing of the whole in a close chamber, substantially as set forth.

Commenting upon the terms employed, Mr. Dyer defined subdivision to be the production of small lights capable of use in lieu of gas jets, at a cost which brought them within reach of the public. The important features of the Edison burner were its great resistance and its slight surface. The patentee believed, and complainants understood it to be the case, that former experimenters had worked in the direction of reducing, instead of increasing, the resistance of the carbon rod. The patentee had not only reversed the preceding practice, but he had made an important discovery upon which that reversal is based, namely, that carbon in a high vacuum has such stability that even a filament made by heating cotton thread out of contact with the air—very fragile and very delicate—even that small burner can be practically maintained in operation.

Reading again from the patent this sentence: "By using the carbon wire of such high resistance I am enabled to use fine platinum wires for leading wires," Mr. Dyer remarked that this was a significant statement, for by using carbon of such high resistance, it was possible to obtain light with minimum current; the small current also made possible the use of fine platinum wires, which could be sealed into the glass and would not heat and crack the bulb. He then read the first and second claims and stated that they were the ones claimed to have been infringed by defendant.

Mr. Dyer then handed to the court the lamps alleged to be infringed by the defendent, one being a Maxim lamp with M-shaped paper carbon, and another having a zig-zag carbon, also of paper. The third lamp had a zigzag burner of Weston tamidine.

Mr. Dyer said that to prevent any misconception of the scope of the patent as contended for by the complainant, he would read from the testimony of Professor Barker, complainant's expert, who was of the opinion that each of the three lamps contained all the elements of the first and second claims, combined and operating in the same way and for the same purpose. The coiling of the filament referred to in the patent was unnecessary when a steady current was employed, since the flickering was no longer appreciable to the eye. The differences in the material of the burners were merely matters of detail.

The invention of Mr. Edison described in this patent had several times been a matter of judicial interpretation and construction. In the English case against Woodhouse and Rawson the validity of the patent and the fact of infringement were both denied. The objections to its validity were, first, vagueness of description; second, insufficiency of instructions to workmen; third, that the patent did not describe a useful lamp, and fourth (a special English defence), that at the time of filing the final specification Mr. Edison knew of a better mode of manufacturing his carbon filament, and fifth, that the invention was not new in view of the state of the art, which embraced practically the same patents and publications as those in the present case, together with the Swan lamp, not available here as a defence, because neither patented nor published. Justice Butt held the patent valid, and the second claim infringed, and thenceforth the English litigation proceeded upon the second claim. This decision was affirmed on appeal January 31, 1887. A second suit was afterwards brought against Holland and others, and was decided by Justice Kay adversely to the patent, principally on the ground of insufficiency of the specification, in that it described certain methods which the court found to be impracticable. On appeal from Mr. Justice Kay, the case was decided by the appellate court, Lord Justices Cotton, Lindley and Bowen, February 18th, 1889, in favor of the patent.

In Germany in 1884, a suit brought to annul the Edison patent as invalid in view of the prior state of the art was decided in favor of the patent March 9, 1885; in a subsequent suit Naglo Brothers were held as infringers, but on May 5th, 1890, on appeal, the decision was reversed, and the Swan lamp made by Naglo held not to be an infringement. In the German case the question arose entirely on the first claim.

He came next to the case of the Consolidated Electric Light Company against the McKeesport Light Company, decided by Mr. Justice Bradley, October 5, 1889. The parties there were practically the same, except that the complainant here was the defendant there. Handing to the court a copy of the Sawyer & Man patent, the subject of that suit, Mr. Dyer said that Judge Bradley decided that what was described in that patent was not new and did not advance the art, but that what was described in the patent here in suit, was new, and was the particular invention which established the art of incandescent lighting. After filing the application for the patent in suit, November 11, 1879, Mr. Edison filed another application claiming paper as an incandescent conductor, thus attempting to patent a particular material which fell within the general scope of the first patent. Soon after Sawyer & Man filed an application upon the same thing; an interference resulted which was contested for several years, and finally decided in favor of Sawyer & Man. After this decision the application was expanded by amendments; Edison was no longer using paper but bamboo, so the application of Sawyer & Man was enlarged to cover fibrous materials generally, and upon that patent suit was brought. It was set up in behalf of Edison, not only that the use of paper was not new, but that Sawyer & Man were proceeding upon principles of construction proved over and over again to be impracticable, whereas that which was practicable, and which established the art of incandescent lighting, was Edison's invention of *the filamental carbon in a high vacuum in an all-glass sealed vacuum chamber*. So that when in this case Justice Bradley passed upon the question as to what the real invention was, all the testimony and all the state of the art was before him. Justice Bradley said that "the great discovery in the art was that of adopting high resistance in the conductor with a small illuminating surface, and a corresponding diminution in the strength of the current. This was accomplished by Edison in his filamental thread-like conductors, rendered practical by the perfection of the vacuum within the globe of the lamp." Again Justice Bradley said: "We think we are not mistaken in saying that but for this discovery, electric lighting would never have become a fact. We have supposed it to be the discovery of Edison because he has a patent for it. This may not be the case; it may be the discovery of some other person, but whoever discovered it, it is undoubtedly the great discovery in the art of practical lighting by electricity."

Having placed before his Honor the patent in suit and having referred to the decisions affecting it, Mr. Dyer said that before entering upon Edison's work he would proceed to explain some of the electric principles underlying the art. He then explained and illustrated by means of diagrams the distinguishing characteristics of the arc and the incandescent lamps; the meaning of the terms electromotive force, resistance and current, and the units of measurement which have been adopted, the whole being admirably illustrated by models showing sections of actual wires and rods of different metals and of different cross-sections. He also explained the difference between the *specific* resistance of a conductor, which depended upon its molecular structure, and its *absolute* resistance, which was determined by its form and size as well as by its material. The enormous difference in the resistance of a metallic and a carbon rod of equal dimensions was well illustrated in one of the models.

Continuing, Mr. Dyer said that the patent spoke of a filament of high resistance and small radiating surface. The radiating surface was quite as important as the resistance. It was important to remember that radiating surface might be varied independent of resistance. So far as resistance was concerned, it was immaterial what the shape of the cross-section might be, but every change in the shape of cross-section changed the extent of the radiating surface. This was illustrated by a model. The next important fact was that the quantity of heat developed in a conductor by the flow of the current was independent of surface, but the temperature to which the conductor was raised by a given amount of heat was directly dependent upon the surface. He desired his Honor to understand, that since the patent called attention to the fact that high resistance and small radiating surface were the objects of the construction, the foregoing explanations had a direct bearing upon the patent. A high temperature was absolutely necessary to produce light economically, and one way of securing a high temperature was by making use of a small radiating surface.

The object of this, and all other inventions relating to incandescent lighting, was to obtain a small light, a substitute for the gas jet for household illumination, and this necessitated a small radiating surface. Mr. Dyer illustrated this point by means of three lamps placed in series, each of 40 ohms resistance, but having different radiating surfaces. When the same current was passed through all the lamps, one showed a very bright light, one was only white hot, and the other barely visibly red.

A high resistance and small radiating surface made possible the use of a small electric current, but aside from the effect upon the light, the quantity of current determined also the size of conductor required to deliver it to the lamp.

Mr. Dyer then proceeded to explain at considerable length the relations existing between the quantity, pressure and energy of the electric current, and the arrangement of the translating devices in series and in multiple arc respectively, pointing out that when the incandescent lamp was to be used for house lighting, the multiple-arc system, making it possible for each lamp to be turned on and off independently, became necessary, and the great obstacle in the way of the use of that system, aside from the question of the practicability of the old lamps themselves, was that by reason of their low resistance and the large quantity of current required to operate them, they could not be placed in large numbers in multiple arc, except by the employment of conductors of enormous dimensions, which would make the cost prohibitive.

These explanations, continued Mr. Dyer, are necessary in order to appreciate the state of the art. An examination of the state of the art disclosed a lack of appreciation of those principles, or at least of such appreciation of them as would enable a practical lamp to be produced. These explanations enabled us to appreciate the function of high resistance and small radiating surface as elements in the economical production of light, and in the distribution of current without a prohibitive cost of conductors. The the function of the high vacuum and of the all-glass construction of electric lamp chamber, as well as a due appreciation of what had been accomplished by the invention in issue, could only be seen after an investigation of the prior state of the art, as it existed in the fall of 1878, when Mr. Edison commenced the series of experiments which resulted in the production, in October, 1889, of the lamp described in the patent in suit. There were two landmarks in the topography of the prior art; the patent of King in 1845, and the resuscitation of the art by Lodyguine in 1873. King described two lamps, one with a platinum burner, not in a vacuum, and another, more important in this case, having a conductor of carbon enclosed in a Torricellian vacuum. Criticising this lamp, Mr. Dyer said that it was admitted by all the experts connected with the case that it was not practicable to make an operative carbon conductor in the way described by King, viz: by mechanically reducing a rod of gas carbon. Again, it was a lamp of low resistance, from 1 to 4 ohms, subject to all the disadvantages pointed out in the patent in suit. It was a series lamp, as appeared by the patent itself, and could not be used in multiple arc. Dr. Morton, one of the experts for the defence, in an article in *Scribner's Magazine*, referring to the lamps of King and others, had said that the problem of commercial electric lighting by incandescent conductors, notwithstanding these inventions, yet remained without a solution. Similar statements had been made by Prof. Cross, another expert for the defense in this case. Prof. Brackett, testifying for the complainant, also showed that the vacuum must be very uncertain. Now it was not enough for the method to be capable of success in individual cases; it must be a method which could be applied commercially, and practically to the manufacture of thousands of lamps.

Mr. Dyer then proceeded to point out the inconsistency of the testimony of the defendants' experts, Prof's. Morton and Cross, in their testimony in the McKeesport case and in the present case, in reference to the lamp of the King patent. He next referred to the Roberts English patent, pointing out that it described a conductor of low resistance made by reducing material already carbonized, and contained in a chamber of a character in which we now know it to be impossible to maintain a vacuum. He further pointed out that the radiating surface and the resistance of the burner played no part in these lamps; inventors had not come to consider these matters; while Edison had taken up the art where the electric light had been produced, and he endeavored to produce it practically; to make a lamp which could be used without enormous expense for conductors, and which should be a simple piece of apparatus that could be handled by the public.

Mr. Dyer next referred to the abortive attempts of experimenters to produce a sub-divided electric light by Geissler tubes, and then took up the consideration of Crookes' radiometer, in which an electric current was passed through a platinum wire enclosed in a sealed and exhausted glass globe, in order to produce a source of radiation within the chamber to act upon revolving vanes. Of course there was no idea of making an electric lamp or a radiating surface or anything of that kind. It would probably not be contended by defendant that these devices directly anticipated the patent, but that the Geissler tube taught constructors of electric lamps how to seal a platinum wire into glass, that the radiometer taught them how to form high vacuum and that there could be no invention in bringing these elements together, as had been done in the patent in suit.

Mr. Dyer then briefly referred to the lamps of prior inventors put into evidence in the case; those of Konn, Lodyguine, and Fontaine.

The period during which these lamps were produced was one of active experimentation, having its centre at Paris. The Jablochkoff candle was then being employed in lighting the streets of that capital, and everything seemed ripe for the introduction of a divided electric light for interior illumination, provided a suitable lamp could be had. To determine the value of known systems of incandescent lighting, Fontaine experimented with several Konn lamps and the results were published in his book in 1877. He says that the vacuum, never being perfect in the receivers, the first carbon was in greater part consumed. There was also a kind of evaporation which continued to slowly destroy the incandescent rods—an evaporation clearly proved by the deposit of carbon on the interior of the bells. Here then, said Mr. Dyer, was a vital defect; notwithstanding the carbons were removed from oxygen and not consumed, yet they were volatilized; they were without stability even in an atmosphere which would not support combustion. What was the effect of this upon the art? Swan, an early English experimenter, forcibly sets forth the effect of the discoveries of Fontaine upon the progress of the art and of subsequent experimentation. He says:—"In all the various attempts to utilize the principle of the incandescence of carbon in vacuum, two great difficulties have stood in the way and baffled every attempt to overcome them. One was the rapid wearing away and consequent breaking of the incandescent carbon, and the other the obscuration of the lamp by a kind of black smoke."

Quoting Fontaine's statements, Swan said: "If this idea of the volatilization of carbon were founded in fact, any further attempt to render incandescent carbon lamps durable by means of a vacuum would be mere waste of time, and durable they must be to be of any practical value." These views were reiterated by Schwendler, writing in 1879. Such was the impression that the discoveries of Fontaine left upon the art, and hence it was of great importance to understand that the art, as it stood when Edison took up the matter, absolutely excluded the idea of obtaining success by the use of carbon. In support of this position Mr. Dyer quoted from an article by Dr. Morton in the *Gas Light Journal* of October 17, 1878; his report to the Lighthouse Board in November, 1879, and the work of Bernstein on electric lighting. The concrete problem was that known as the sub-division of the electric light. The electric light had its commercial embodiment only in the arc-light; the great problem awaiting solution was a sub-division that would furnish lights comparable with an ordinary gas jet, which could be turned off and on at the will of the user. Commercial considerations required that subdivision should be economical; that one generator should operate a considerable number of lights situated at considerable distances. Other conditions were that the first cost should not be excessive and the operation simple and certain. It was a matter of very great moment to defendant that the court should understand that each prior experimenter not only believed that a carbon lamp could not be made durable, but that the incandescent lamp could not be used in large numbers to produce small lights. Mr. Dyer, after reading from Fontaine's book the account of the celebrated experiment in which he believed he had disproved the divisibility of the electric light, repeated the experiment with a group of lamps connected with a battery, demonstrating that a current which brought one lamp to a condition of brilliant incandescence was insufficient to render five lamps visibly luminous. Mr. Dyer explained that the fallacy underlying these experiments was the assumption that the smaller lights should be produced by passing a smaller current through the same lamp; for in such case the burner had a lower temperature and as the temperature decreased, the light diminished in an enormously greater ratio. Had Fontane known how to construct lamps of high resistance and small radiating surface, he would have come to a different conclusion as to the possibility of subdividing the electric light. Mr. Dyer then illustrated this point by exhibiting five lamps of high resistance and small radiating surface, showing that under these conditions each of the five lamps gave its full quota of light, and was not materially affected by turning the others off and on. "This, your Honor," said Mr. Dyer, "is success; the other may be characterized as failure." At this point the court adjourned for the day.

The next morning, Mr. Dyer, resuming his argument, said:—Early in October, 1878, great publicity was given through the daily press to the announcement that Mr. Edison had discovered an electric light which solved the problem of sub-division, and could be supplied with great economy. Thereupon the question became a matter of discussion, and various men of science conscientiously believing that sub-division was impossible, or its accomplishment remote, felt called upon to express their opinions, in order to allay the commercial disturbance due to the great depression in the gas interests caused by the announcement of Edison's discovery. The deductions of Fontaine were mathematically proved to be correct, and the subdivision of the electric light was pronounced practically and theoretically impossible. Mr. Clarke, a witness for the complainant, has collected and placed in the record many pertinent extracts showing the general acceptance of Fontaine's demonstration, and the subsequent mathematical proof, furnished by Mr. Preece, a noted English electrician, that the light, with lamps in series, decreases as the square of the number, and in multiple-arc as the cube of the number. Says Mr. Preece: "It is this partial success in multiplying the light that has led so many sanguine experimenters to anticipate the ultimate possibility of its extensive sub-division—a possibility which this demonstration shows to be hopeless, and which experiment has proved to be fallacious." Similar expressions of opinion were read by Mr. Dyer from a letter of Prof. Silvanus Thompson in *Engineering*, in 1878, and from the testimony of scientific writers before the parliamentary committee in 1879. He also referred briefly to the work of others contemporaneous with Mr. Edison, to show that, with the exception of Lane-Fox, nobody except Mr. Edison appreciated the conditions upon which success was to be obtained, and he (Lane-Fox) only as an unattained desideratum, for he made no practical suggestion for obtaining those ends. And in respect to this, it appears by the record that Mr. Edison was prior to him in that appreciation, and so far as reaching a practical lamp goes, Mr. Edison reached that first. In 1879 appeared another edition of Fontaine's book, from which extracts were read tending to show that no subdivided incandescent lamp was known at that time. The work of Sawyer & Man, which appears at length in the record, was carried on contemporaneously with that of Edison. It was sufficient for the present to say that the entire matter was investigated by Mr. Justice Bradley, with the result already before his Honor, the conclusion being that they were pursuing the wrong principle and did not reach success. Mr. Dyer then referred to the experiments of Farmer with the platinum lamp, as given in the publications of Prescott and of Sawyer, and then passed to the consideration of the Lane-Fox patent. Quoting from the English decision, in which the court, among other things, said, "When he comes practically and finally to deal with the matter, he disclaims it and drops it out of his patent. Why? Evidently because he did not know how to make an efficient carbon conductor. The carbon conductor he describes—he must have thought, and he says in fact—was less desirable than the metallic under all circumstances; and he did not know how to make one that would be better."

That Lane-Fox had very clear and advanced notions as to what was necessary for a practical system no one could doubt. The closing paragraph of his letter in the London *Times* of December 26, 1878, evidently refers to his own experiments with incandescent lamps, and to the hope he had that he would yet be able to make a practical lamp. He undoubtedly had the ambition to be first in that respect, but that he was not first, he himself admitted in a discussion before the Royal Institution in 1881. Sir William Thomson, probably the foremost electrical engineer of the time, when asked how in the fall of 1879 he would have had advised the placing of 500 incandescent lamps, had replied: "I should certainly have advised against any such arrangement, as no incandescent lamp was known at that time which could possibly have given a satisfactory result." Mr. Edison's work in the fall of 1878 and the early part of 1879, prior to the actual grant of the Lane-Fox patents, showed that he had the same appreciation of high resistance and small radiating surface earlier than any effective date which can be given to the Lane-Fox patent in this country, and Mr. Edison could not have received from those patents his knowledge of the necessity of high resistance and small radiating surface. The testimony in the Sawyer-Man interference, in evidence in this case, furnishes material from which we can gain an idea of Mr. Edison's work, and in the present case also the defendant called Mr. Edison and examined him somewhat cautiously, getting from him statements which furnished additional material of like character. It appears that in 1877 Mr. Edison made experiments which demonstrated that carbon had no considerable life under conditions then attainable, and the experiments were discontinued until renewed in the fall of 1878. Sketches in the record show that even at this early period Mr. Edison appreciated that for a multiple-arc arrangement of lamps he needed a high resistance. In August, 1878, he resumed work. Experiments upon incandescent carbon under the receiver of an air-pump were hardly more successful than those of the previous year, but proved that carbon was an unsuitable material under the conditions then obtainable. Mr. Edison testifies: "Our calculations showed us that the lamp must have at least 100 ohms resistance to compete successfully with gas." He further says that he knew he could get the requisite resistance and small radiating surface by means of carbonized paper or wood, and therefore while working to accomplish this by means of platinum, he endeavored by a more perfect vacuum to obtain incandescent conductors of carbon which would give the result. "*The great point we desired,*" says Mr. Edison, "*was a lamp of high resistance and small radiating surface, and it did not matter very much whether it was of carbon or of platinum.*" The platinum lamps to which he refers are shown on the chart (indicating), one being the platinum lamp of 1878 and the other of 1879. The latter has a platinum wire wound on a bobbin and sealed into an all-glass globe, the highest perfection probably ever reached by a platinum lamp. But, as Edison testifies, notwithstanding the platinum was in a high vacuum, it was still subject to disintegration, the phenomenon which prevented all platinum lamps from being a success. Respecting the transition from the platinum to the carbon filament lamp of the patent in suit, Mr. Edison, testifying in 1881, stated that when he had ascertained that he could get a high vacuum with a Sprengel pump, it occurred to him that perhaps a filament of carbon could be made to stand in the sealed glass vessel, exhausted to a high vacuum, which he was then using, and in October, 1879, he made lamps of paper carbon and of common sewing-thread, placed in a receiver made entirely of glass and exhausted to nearly one millionth of an atmosphere. "We had reached the condition," says Mr. Edison, "where, notwithstanding the carbons were small in mass and filamentary, they were stable sufficiently so to allow of the economical subdivision of the electric light and the possibilities of competing commercially with gas." "It was the new conditions which caused this lamp to be a success, which conditions were high vacuum in a receptacle in which no deterioration or lowering of the vacuum occurred to destroy the carbon." "It was the discovery of the stability of carbon, even when filamentary, enclosed in a high and stable vacuum, which made the modern incandescent lamp possible." . . . . "It was in that particular lamp that I discovered this all-important fact, that something which was expected to take place, did not take place; and this discovery permitted the use of fine filaments and carbon of high specific resistance, and made incandescent lighting, as we know it, commercially practicable." Being asked what led him to expect that if the carbon was placed in a highly exhausted all-glass vessel it would remain stable, Mr. Edison replied: "I thought that it would remain stable as far as oxidation was concerned, but I did not, as I stated before, think it would stop the disintegration of it entirely, because I had read something about incandescent lamps, and it seemed that they all universally stated that there is a deterioration; that a great many persons who have experimented with incandescent lamps stated that there is a blackening of the globe. Now, this blackening could not be due to oxygen, because the oxygen would form carbon monoxide. I saw, independent of the oxygen, there must be the matter of disintegration that I was afraid of, but I thought that perhaps that, having got rid of all oxygen, this distribution would not be so large a factor as to prevent the use of a lamp for commercial purposes.

"It is to this discovery," continued Mr. Dyer, "that we wish to appeal, as showing beyond all doubt that there was invention in this lamp produced by Mr. Edison, and invention of the very highest character." Referring to the 1878 experiments, Mr. Edison's principal assistant, Batchelor, says: "Our conversation frequently was directed to getting the highest resistance in the least possible space. I remember once or twice during these conversations early in 1879, Edison remarked, 'How easy it would be to get this resistance if carbon were only stable.'" Mr. Upton, another assistant, testified that he measured the resistance (cold) of one of these carbons, which was then burnt for a number of hours and again tested and no change found in its resistance. "I remember," says Mr. Upton, "that we all felt very much elated at the carbon not changing its resistance, for it showed that there was no wasting away of the carbon."

Mr. Dyer then exhibited drawings showing the evolution of the Edison lamp, beginning with the one in which the discovery of the stability of carbon was made, passing to the lamp of the patent; the lamp of November, 1879, and finally the bamboo lamp now made. He then described the successive steps of the process by which the carbonized bamboo burner was made and mounted in the lamp. He next exhibited samples of conductors of the thickness required to feed 100 16-candle lamps 100 feet from the generator at 110 volts pressure, and compared with that a bunch of 400 similar wires, such as would be required to accomplish the same thing with the old lamps having the carbon rod. Mr. Dyer said this illustrated, more forcibly than could be done by figures, that to use a lamp of that kind in multiple arc the cost would be absolutely prohibitive. Mr. Edison's experiments had shown that the carbon in an atmosphere of nitrogen at atmospheric pressure, the method adopted by Mr. Sawyer, required nearly twice as much electricity to produce the same candle power as when the burner is in a high vacuum. The vacuum itself is a cause of great economy. The defendant has attempted to show that even in the modern lamp there is a gradual blackening of the globe, and will probably argue that there was no discovery of the stability of carbon by Mr. Edison, because, as a matter of fact, carbon is not stable, even in the modern lamp. This disintegration does go on, even in modern lamps, but not enough to make the lamps uncommercial, and there was, indeed, a discovery in finding how disintegration might be reduced and the lamp lifted from failure to success. Defendant may argue that it is simply a matter of degree, but that which can turn failure into success certainly could not be so characterized.

The invention having been made, it remained to find the best material for the purpose and the most suitable form to give the burner. For his first public essay Mr. Edison employed carbonized Bristol board in horseshoe form. In December, 1879, a private exhibition was given, and near the end of the same month a public exhibition attended by thousands of visitors.

Mr. Dyer then briefly outlined the commercial development of the incandescent lamp in Mr. Edison's hands. After this exhibition, he said, the criticisms of scientists and electricians were renewed. In this second attack, as before, Dr. Morton was in the van, hastening to pronounce that a failure which he had not seen. He read Dr. Morton's letter in the *Sanitary Engineer*, and an interview in the *New York Times*, published December 28th, 1879, in which he said: "All attempts up to the present lamp in this direction are acknowledged to be failures, and as I have pointed out there does not seem to be any novelty which would authorize us to hope for a better success in the present one." The journals were full of criticisms of the same character. Then came an account of Mr. Edison's light by Mr. Upton in *Scribner's* magazine in February, 1880, which was the occasion for a renewed attack by the writers and critics. Secure in the possession of a practical lamp, Edison continued his work, feeling that scientific ignorance must finally give way in the face of commercial accomplishment. Actual tests by Professors Rowland, Barker, Morton, Brackett and others, and the commercial introduction of the lamp, soon confirmed the accuracy of the claim advanced for Mr. Edison, and showed that the electric light could be subdivided and that the lamp was a durable one. But the skepticism of the European electricians was not overcome until Edison exhibited his apparatus at the Paris Exposition in 1881, at the close of which Mr. Edison was awarded diplomas, medals, etc., and finally an especial diploma of honor, and the decoration of the Legion of Honor. The report of the Exposition commission shows, that although there were infringers and imitators present, yet Edison was in the van of progress, and was making the best lamp in the market. and has continued in that position to the present time. In the spring of 1880, the steamship "Columbia" was lighted with Edison paper carbon lamps; later in the same year, bamboo, which has ever since been used, was adopted as the basis for the carbon filament. It appears by an official bulletin of April 6th, 1883, that a central station plant had then been in operation in New York city for several months without stopping night or day. By October 31st of the same year, the station was lighting 508 houses wired for 12,000 lamps. The business has since grown to enormous proportions, with capital invested aggregating tens of millions and at the present day the number of lamps alone manufactured throughout the world by a conservative estimate is between 75,000 and 100,000 per day. Complainants therefore claim for the invention of Mr. Edison the merit of great utility, and for his patent that liberality of construction which the courts in the past have applied to patents upon inventions of this character.

The defendant's experts take the position that, in view of the state of the art, no invention was required to produce the lamp of the patent in suit. If these experts could not at once have made the perfect thing, the difficulties met could have been remedied, they think, as they arose by an intelligent application of existing knowledge. He would leave this position to the court without discussion, were it not that it afforded an opportunity for the criticism of these gentlemen, in the capacity of experts competent to instruct the court upon this subject. These same gentlemen, when the necessity arose in the McKeesport case, for making a place in the art for the Sawyer and Man arch-shaped fibrous carbon, treated the prior state of the art as entirely inadequate to supply a practical device. A large gap existed in the art, which it was necessary to fill before incandescent lighting could become a commercial fact. Judge Bradley agreed with them that the gap existed, but decided that it was not filled by the arch-shaped fibrous carbon of Sawyer and Man, but by the filamentary burner and high vacuum of Edison. Now that there is a change of attitude, these gentlemen find no difficulty in disagreeing with their former testimony and with the decision of Judge Bradley, and they say there was no gap at all. What reliance can be placed upon statements of facts or expressions of opinion given by these experts?

In an article in *Scribner's Magazine*, for August, 1889, while the McKeesport case was under consideration, Dr. Morton said:—"The problem of commercial electric lighting by incandescent conductors yet remained without a solution. This was the state of affairs up to the fall of 1878," adding that at that point of time, Sawyer and Man came in and solved the entire difficulty. He continued: "It is to Mr. T. A. Edison, without doubt, that we owe many of the simplifications and modifications, which, by cheapening the lamp and diminishing its weight, have extended its range of use and its usefulness to a remarkable degree." If Sawyer and Man had succeeded in the McKeesport case, it would be quite immaterial whether Edison had improved upon that lamp. Justice Bradley has removed Sawyer and Man from the prominent position given them in the art by Dr. Morton, but there is left a beneficial residuum, viz., that the problem remained without solution, and that what Edison did extended the range of usefulness of the electric lamp in a remarkable degree.

As to Professor Cross, it appears from the record that his opinions vary with a change of client and a change of retainer. He was employed by the complainant company, when it contemplated bringing suit in 1881, on the same patent against the same defendant, and against the same lamp—the M lamp. In reply to specific questions, after examination of the patents and publications, he concludes that the Edison patent describes a practical advance in the art; that such advance in the art was made use of in defendant's lamp, and that defendant's lamp was of "high resistance," although only of 43 ohms; judging from his deposition in this case, his views now seem to be entirely changed.

With regard to the construction of the patent, Mr. Dyer said he would briefly allude to the question of the meaning of the term "filament of carbon," appearing in all the claims as descriptive of the lamp burner. Both in the English litigation and in the present suit, it had been contended that the definition was vague, indefinite and uncertain; and that a determination of the meaning of the term is necessary in order to exclude old and include new lamps; that is, the defendant's lamps. Complainant would contend that this mathematical certainty is not necessary. So long as defendant's lamps are distinctively of a filamentary character, there could be no reason for a discussion as to how much larger they might be and still be within the terms of the patent. He would hand his Honor a lamp put in evidence to show the distinctive filamentary type of the largest carbon used by defendant. Defendant has suggested that the proper construction of the term "filament" may be a burner of at least 100 ohms resistance hot, this being about one-half its cold resistance. The object of that contention was this: Under the present affiliation of defendant with the Westinghouse company, a system had been introduced of distributing electricity by alternating currents at high pressure which made possible the use of lamps of 50 or 60 ohms resistance. So if defendant succeeds in that contention, they will be able to go on with their business in future under that system using lamps of less than 100 ohms hot. The patent office model shows what Edison contemplated under the patent. A lamp made in the proportion of the model, measured 80 ohms cold and 40 ohms hot; practically the same as the lamp of defendant about which this question arises. As a matter of fact, defendant's M lamps have been used in multiple-arc circuits in large numbers.

The difference between the filamentary and the rod lamp is shown in tables which have been prepared. From the patent the smallest filament has been taken, said by Prof. Barker to be five-thousanths of an inch diameter after carbonization. Then a number of the old lamps; Sawyer & Man; millimetre carbons; Adams' lamp; Sawyer feeder lamp, etc. Referring to the second column, giving ratios of cross-sectional areas, the filaments run from 1, the smallest tar-putty filament, to 9, and then jumps from the largest filament to the smallest rod; from 9 to 39. Conversely, resistance being inversely as the radiating surface, we have in the next table, with the largest rod as 1, a jump from the smallest rod at 16 to the largest filament at 69. In the last two columns of table 2 the ultimate comparison is reached; the ratio of surface per unit of resistance. The largest filamentary burner is placed at 27 and the smallest rod at 244; and if to this is added the difference in specific resistance, which is believed to be fair under the circumstances, the result for the largest filamentary burner is 27, and the smallest rod burner 1220; the smallest filament in the patent is worth 2,500 times the millimetre rod for the purpose of giving light commercially.

So far as the record has been investigated down to the present time, it would appear that Mr. Edison was entitled to a broad claim for the combination of a carbon burner, irrespective of its dimensions, with a vacuum chamber of this particular character. The real scope of his invention was broader than the filament, though that particular form was necessary in order to make it a practical success. The patent is limited to, or describes, that; but on the broader ground of his discovery of the stability of carbon, a liberal construction should be given to his claim.

At the last moment, defendent found that Dr. Isaac Adams had made what they call a lamp, having a carbon burner in such a chamber, years before Mr. Edison made this discovery and invention This was undoubtedly an absolutely abandoned experiment, and need not be dwelt upon. No sample has been preserved; no publication was made. A patent was applied for in 1882; a rejection was had upon Edison's patent; the rejection was accepted and the claims restricted. Whatever else it might have been, it was a lamp of large radiating surface and low resistance.

In conclusion, Mr. Dyer said that if he had succeeded in clearing away some obstructions in the line of sight, so that argument might henceforth be carried forward with less labor of both court and counsel, his duty would have been successfully performed.

Mr. Wetmore asked whether complainant claimed that the carbon filament of the second claim is one requiring a high resistance irrespective of its specific resistance. Mr. Dyer replied that it meant a carbon conductor of small cross-section and great tenuity. Its resistance depended upon its length, which might be longer or shorter. "That is to say," said Mr. Wetmore, "if a filament of great tenuity had only four ohms resistance it would fall within the claim." "I take it, your Honor," said Mr. Dyer, "that this is a discussion wholly irrelevant to this case. Here is the same attempt that was made with our witnesses." "I don't know about that," interposed his Honor, "The question has presented itself to my mind, and I would like to know if my understanding upon that point is correct." Mr. Lowrey said that complainant understood the claims to state explicitly what it was intended to claim. Infringement of the first claim would be claimed wherever there was a carbon filament of high resistance. Counsel had been retained to prosecute these three infringing lamps, but if a categorical question was asked as to whether a filament of four ohms was or was not within the second claim, his reply would be that he had not been retained to have an opinion on that subject, and did not know anybody who had. Mr. Wetmore said he did not think his question had been answered. It was a very important point in determining the construction of the second claim. Mr. Lowrey replied that all filaments relatively to their length had a high resistance, which Mr. Wetmore insisted was no answer at all. Complainant's counsel, he said, had drawn a broad distinction between conductors of low and of high resistance. He wanted to know whether that limitation applied to the second claim of the patent, because, neither from anything that had been said, nor from the record, nor from counsel's brief, had he been able to ascertain whether that claim was made or not . Mr. Lowrey said he should ask to have each of the three lamps in evidence convicted under both claims; with respect to the four ohm lamp, he was content to wait until the case arose. He was not instructed.

His Honor observed that the same question had arisen in his own mind, and he had found difficulty in answering it.

Mr. Lowrey said it was only when the facts were known that the difficulty was perceived of dealing with it except in an actual case. Mr. Wetmore contended that the claim ought to be explicit enough to answer so plain a question without reference to a particular case.

His Honor having intimated that he should like further information as to the difference between "series" and "multiple-arc" distribution, Mr. Lowrey gave a very clear and felicitous explanation of the matter, in which he was effectively aided by Mr. Dyer, after which the proceedings were adjourned for the day.

DECISION AGAINST THE NEW AMERICAN CO., ON DOUBLE CARBON LAMPS.

A decision was rendered in the United States Circuit Court by Judge Shipman, last week, in the suit of the Brush Electric Light Company against the New American Electric Arc Light Company to restrain the latter from using certain lamps, as they were an infringement upon Brush patents. In deciding for the Brush Company, Judge Shipman held that arc lamps in which two pairs of carbons are adjusted independently so as to burn successively were infringements upon the plaintiff's patents.

END OF THE EDISON LAMP SUIT ARGUMENTS.

The arguments in the infringement suit of the Edison Electric Light Company against the United States Electric Lighting Company were concluded before Judge Wallace in the United States Circuit Court, Thursday afternoon last, Mr. Dyer having been followed by Messrs. Seward and Lowrey on the Edison side and opposed by Messrs. Duncan, Wetmore and Betts, for the defence. The arguments attracted large audiences throughout. Judge Wallace said that he would announce his decision as soon as possible. He intimated that it was doubtful if he would announce it by July 1st, after which time an appeal would go to the Circuit Court of Appeals about to be organized. In the event of a decision before July 1st, an appeal would be heard in the United States Supreme Court. The models and exhibits will be sent to Syracuse, where Judge Wallace will examine them.

A DECISION IN FAVOR OF "EARTH RETURN" FOR ELECTRIC RAILWAYS.

The Supreme Court of Ohio, on June 2nd, rendered a decision, reversing the lower court in the case of the Cincinnati Incline Plane Railroad Company vs. the City and Suburban Telegraph Company, brought up on error to the Superior Court of Cincinnati. This involves the two great interests of telephone exchanges and electric street railways, and affects the city largely, as well as others adopting the improved and advanced system of street railways.

The action was brought by the telegraph or telephone company to enjoin the Incline Plane Railway Company from constructing and running their electric railway by the use of the Sprague, single trolley system, on the plea that the "earth return" interfered with the use of the telephone, and almost destroyed their business.

The telephone company claimed the first right to the earth, with the use of it for their return circuit. The matter could be remedied by one of two ways. First, by the railway putting in what is known as the double trolley system, by the use of which the telephone would not be interfered with. Second, by the telephone company, instead of using the earth for the return circuit, putting in "metallic circuits."

The finding of the court upholds the theory that the street is primarily intended for the use of the general public for the purpose of traveling and transporting goods, and the fact of motive power, which facilitates the object, being changed to something which might interfere with a subordinate use of the highway, ought not to make any difference in that regard.

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED JUNE 2, 1891.

Alarms and Signals :—

Electric Annunciator System, L. M. Pinolet, 453,416. Filed Sept. 25, 1890.
A system for hotels and other buildings. Instead of a separate drop or other indicator at the office or central point for each room or station the inventor employs a single indicating apparatus consisting of rotating concentric discs, adapted to display successively the desired numbers.

Circuit Closer for Burglar Alarms, E. A. Darling, 453,466. Filed Jan. 10, 1888.
A circuit closer adapted to be operated by the pressure of the foot when stepped upon.

Distribution :—

System of Electrical Distribution, F. A La Roche, 453,597. Filed May 17, 1890.
A system of parallel-circuit distribution. To avoid the fall of potential upon mains of considerable length, the inventor employs two generators of equal electromotive force, connecting the positive main at each end to the positive poles of the generators, and the negative lead, similarly, to the negative poles of the generators. The system is shown modified to include several generators similarly connected and distributed over a long circuit.

Dynamos and Motors :—

Electro Magnetic Engine, C. E. Kells, Jr., 453,260, Filed Feb. 24, 1891.
Employs an electro-magnetic clutch in series with the field-coils of a motor, and a circuit-breaker for stopping and starting the motor. Especially adapted for use with dental engines and similar machines.

Safety Device for Dynamos, C. G. Young, 453,281. Filed Mar. 31, 1890.
A device to effect the automatic opening of both out-going and in-coming circuits upon the occurrence of a ground upon either.

Automatic Switch for Electric Motors, R. McRae, 453,287. Filed Aug. 27, 1890.
A centrifugal governor adapted to control the speed of an electric motor.

Switch for Electric Motors, F. A. Wessel, 453,318. Filed Jan. 9, 1891.
An automatic rheostatic switch for regulating the speed of an electric motor.

Automatic Starting Switch for Electric Motors, F. A. Wessel, 453,319. Filed Jan. 9, 1891.
Similar to the next above.

Automatic Starting Switch for Electric Motors, F. A. Wessel, 453,320. Filed Jan. 9, 1891.
An automatic rheostatic switch controlling the admission of current to a motor.

Starting-Switch for Electric Motors, C. C. Haskins, 453,367. Filed Oct. 24, 1890.
A rheostatic switch, including a pivotal arm or finger controlled by a spring to return automatically to the off-point from any position.

Lamps and Appurtenances :—

Bracket for Electric Lamps, T. C. Smith, 453,248. Filed May 19, 1890.
A bracket especially adapted for supporting shunt-coils, converters, etc., and their connecting wires.

Detachable Rosette, C. E. Davis, 453,337. Filed Dec. 31, 1890.
A rosette fuse-block for use with pendant incandescent lamps.

Switch-Board for Electric-Arc-Light Stations, E. R. Sawyer, 453,349. Filed Oct. 23, 1890.
Details of construction and arrangement of circuits. A plug switch.

Electric Lamp Socket, Le R. S. White, 453,455. Filed Apr. 1, 1891.
Details of construction and method of securing the parts together.

Electric Arc Lamp, W. Hochhausen, 453,583. Filed May 28, 1890.
Relates to the feed regulation appliances, the transferring mechanism for double-carbon lamps, and to devices for suspending the lamps.

Medical and Surgical :—

Magneto-Electric Machine, W. Humans, 453,242. Filed July 23, 1885.
A machine for medical purposes.

Electrical Apparatus for Surgical Purposes, C. B. Harness, 453,476. Filed Jan. 26, 1891.
Apparatus for the treatment of patients preparatory to and during surgical or dental operations, and intended to diminish pain or render patients insensible.

Metallurgical :—

Method of Magnetic Separation, H. C. Townsend, 453,317. Filed Sep. 27, 1890.
Consists in establishing a flow or stream of liquid, such as water, in which the materials are carried in divided form, and producing in the stream two flowing strata, in one of which the magnetic material is retained by magnetic action opposed to gravity, and diverting the stratum containing the magnetic material through a channel separate from that through which the stratum holding the non-magnetic material passes.

Miscellaneous :—

Advertising Device, S. D. L. Jackson, 453,190. Filed Oct. 53, 1890.
An apparatus including a signal and a portable source of electricity.

Electric Connector, F. Wheeler, 453,225. Filed Dec. 30, 1890.
Designed to obtain an immediate and automatic separation when from any cause an unusual tension strain occurs.

Pole for Electric Wires, C. A. Lieb, 453,286. Filed Nov. 3, 1890.
Composed of metal strips or wire wound in a tapering spiral, the convolutions being united together, and a filling material within to reinforce the structure.

Electric Current Tester, W. H. Ebert, 453,323. Filed Feb. 20, 1891.
Provides a source of current for testing purposes consisting of a pair of electrodes adapted to be placed one over and one under the tongue.

Process of Coating Metals with Oxides, A. E. and A. G. Haswell, 453,363. Filed Nov. 3, 1890.
Process of electro-depositing binoxide of lead and binoxide of manganese on iron and steel. Consists in immersing the article to be coated in a bath containing nitrate of lead, nitrate of protoxide of manganese and nitrate of ammonia in solution, and in depositing binoxide of lead and binoxide of manganese by passing an electric current through the bath. First claim includes only the deposition of binoxide of lead.

Electrical Typewriting Machine, J. F. McLaughlin, 453,430. Filed Aug. 18, 1887.
Employs electro-magnetic apparatus for controlling the action of the letter-spacing pawl lever.

Electrical Register for Measuring Pumps, R. Jewell, 453,484. Filed June 20, 1890.
Especially adapted for registering the quantities of beer discharged from beer engines or pumps.

Automatic Electric Switch, R. Baumann, 453,572. Filed Nov. 7, 1890.
A cut-out adapted for use with heavy currents.

Railways and Appliances :—

Electric Street Car Motor, J. F. Shawhan, 453,216. Filed Sept. 9, 1889.
Consists of an electric motor having two independent revolving armatures, connected by gearing with independently revolving axles of the car. Shows a novel arrangement of gearing.

Insulating Cover for Trolley or Conducting Wires for Electric Railways, A. L. Ide, 453,326. Filed Dec. 31, 1890.
The trolley-wire is but partially enveloped by an insulating material. The insulation protects the upper surface of the conductor, leaving the lower surface exposed for contact with trolleys.

Railway Signaling Device, W. A. Luby, 453,447. Filed Nov. 26, 1890.
For signaling to a train on its approach to a station the condition of the track ahead of it or the dangerous or safe condition of switches. Acts automatically.

Electric Railroad-Signal Alarm, N. S. Chapman, 453,578. Filed Feb. 18, 1891.
Provides for an alarm to two trains approaching each other on the same track, for notifying the engineer of an open switch, and enables the engineer to test the batteries conveniently.

Telegraphs :—

Telegraph Receiver, C. Langdon-Davies, 453,261. Filed Nov. 18, 1890.
Relates to telegraph receivers for vibratory impulses and to the apparatus shown in the same inventor's patent Mar. 25, 1890, No. 424,006.

Sextuplex Telegraph, T. A. Edison, 453,601. Filed June 2, 1877.
At either end of a line one receiving magnet responds to reversals of current while the other two respond to an increase or to a decrease in the strength of the current independently of its direction.

Telephones and Apparatus :—

Holder for Telephone Receivers, F. T. and W. K. S. Tinning, 453,433. Filed Mar. 5, 1891.

Telephone Circuit, W. W. Jacques, 453,483. Filed Mar. 7, 1891.
Designed, with a given number of metallic circuits, to increase such number without adding additional wires and without changing the electrical conditions of the original circuits.

Telephone Transmitter, P. Fitzsimons, 453,581. Filed Sept. 9, 1890.
A carbon microphone.

Mechanical Telephone. J. P. Sunderland, 453,600. Filed Sept. 22, 1888.

LIGHTING THE HARLEM TUNNEL.

The State Railroad Commissioners have heard further statements and opinions as to lighting and ventilating the Harlem tunnel. Mr. W. J. Hammer advocated incandescent lighting. Mr. H. C. Ulman proposed arc lights concealed in the roof of the tunnel. Any use of lights was opposed by two of the locomotive engineers, who wished the only lights to be signals. L. J. Wing, representing the L. J. Wing Company, of No. 126 Liberty street, gave an interesting explanation of a plan to ventilate the tunnel. Mr. Wing's plan involved the closing of all the openings in the tunnel at both ends, except when a train is entering or leaving it, and proposes a system of rotary fans, continually exhausting the air from the tunnel and discharging it through three towers, the height of which, of course, could be made sufficient to prevent nuisance to people living along the line. Mr. Wing said the system was in successful use in the tunnel under the Mersey, in England, and in many collieries and other places.

NEW YORK SUBWAYS.

Mayor Grant threatens to forfeit the Subway Company's bond of $250,000, on the ground that it has not got its subways finished on time.

BID WANTED IN TEXAS.

Larmour & Watson, architects, Austin, Tex., want bids until noon of June 24, on an electric light plant for the Southwest Texas Insane Asylum. The plans and specifications can be seen at their office; also at the buildings, near San Antonio, Texas.

TRADE NOTES AND NOVELTIES

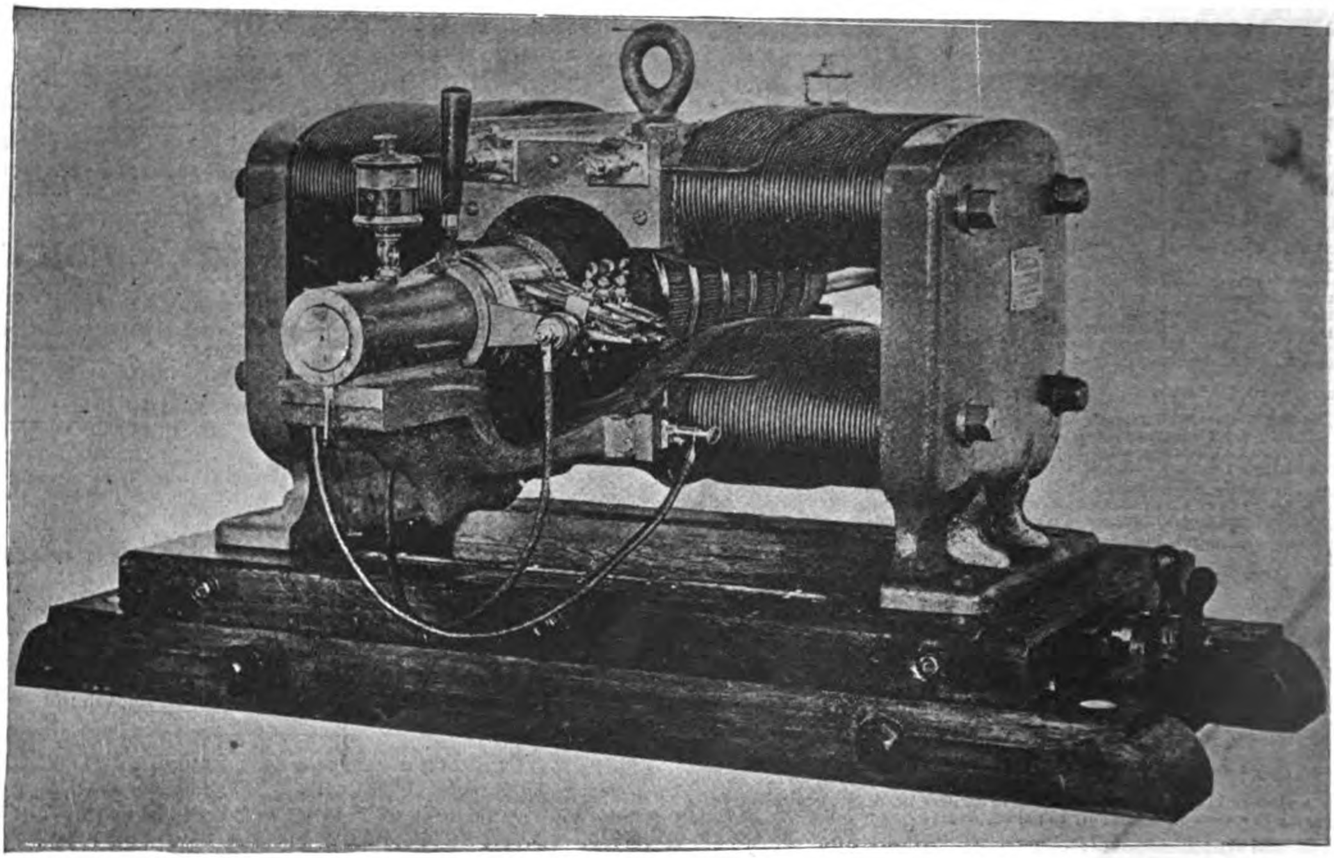
AND MECHANICAL DEPARTMENT.

Don't be afraid to let people know you are in business.

THE FONTAINE DYNAMO.

THE accompanying illustration represents the dynamo manufactured by the Fontaine Crossing Co., of Detroit, Mich. These machines are especially adapted to use in mills, shops, factories, and steamships. They are entirely self-regulating, and especial attention has been given to the mechanical construction of the working parts, with smooth running and high efficiency as the result.

One of these dynamos is now on board the "E. C. Pope," the largest freight steamer on Lake Michigan, operating the equivalent of 225 16 c. p. lamps, at a speed of only 450 revolutions, and is running smoothly and noiselessly.



THE FONTAINE DYNAMO.

These dynamos are shunt and compound wound, with drum armatures, of very low resistance, and run at a very slow speed, beside possessing the other points inherent in good machines.

LIGHTING THE WORLD'S FAIR WORK.

Prof. John P. Barrett of the Department of Electricity of the World's Columbian Exposition, has visited Jackson Park with a view to selecting a suitable location for establishing an electric light plant, during the period of construction. He considers that the proper and most desirable place for this station, is on the west side of the park, opposite 63rd street, and the probable cost will entail an expenditure of some $20,000, and in the neighborhood of 200 arc lamps will be required for the work.

ELECTRICAL FIBRE CARBON CO.

The above concern, of 1234 & 1236 Michigan avenue, Detroit, Mich., are now in the field manufacturing improved galvanic batteries, and they claim to have the best and most economical form now on the market. They say, "Its construction is excellent for a wet battery. It is self-contained. There is no creeping of salt, no breakage of glass jars, no attention needed after filling with water, while its best quality is that of outwearing any other battery of its sizes that cost twice as much money." Their factory is well equipped for the manufacture of superior carbon elements, and under their patents they make extra large carbons. In fact, their methods and processes enable them to mould carbon elements, "into any size that iron castings have ever been produced in." The company is strongly organized, having John R. Markel as president, J. H. Davis as vice-president, and Eugene Klein as secretary and treasurer.

PARTRICK & CARTER CO.'S CANADIAN AGENCY.

The above enterprising Philadelphia house have made arrangements with the Toronto Construction & Electrical Supply Co., of Toronto, Can., for a general Canadian agency, which will carry in stock a full supply of their annunciators, alarms, bells, pushes, batteries, etc. This arrangement has been made for the convenience of the trade in general, and will enable a great many, who have desired to use the Partrick & Carter specialties more extensively, to do so, free from the delays of transit and the heavy charges of transportation. The prices will be very nearly those of Philadelphia, any difference being practically offset by the saving in time, freight charges, breakage, etc.

THE MILLIKEN COMBINATION POLE.

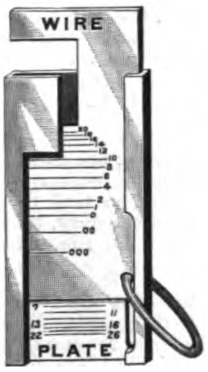
Messrs. Milliken Bros., New York City and Chicago, report a large increase and demand for their patent poles for electric street railway and electric light use. They have lately booked orders for a large number of poles for the Pittsfield Electric Light Co., a new form of combination pole for both street railway and electric light wires. They have also received orders for Los Angeles, Cal.; Little Rock, Ark.; St. Louis; Plainfield, N. J., and Brooklyn. Parties in Wilmington, Del., have found it to their advantage to use poles somewhat similar to the large poles which this concern lately furnished to Passaic, N. J., and which are known as the largest street railway poles in the world. The arms for these poles are only a trifle shorter than the poles supplied to Passaic. Those who desire a first-class pole for street railway work cannot do better than write these parties for their handsomely illustrated catalogue, which gives full information. They are furnishing a large number of poles to South American countries, and report business very brisk.

THE CENTRAL ELECTRIC CO.

As an indication that electrical construction is beginning to pick up in earnest, the Central Electric Company report a largely increased demand for soldering torches of various kinds. This company carries a large assortment of these goods and handle all the most approved styles.

The Bain "break" insulator, handled by the Central Electric Company, is having a ready sale, and is fast growing in popularity with electric railroad men, who use it for insulating span wires. The electric light companies are also ordering them in considerable quantities to insulate suspended arc lamps.

A NOVEL WIRE AND PLATE GAUGE.

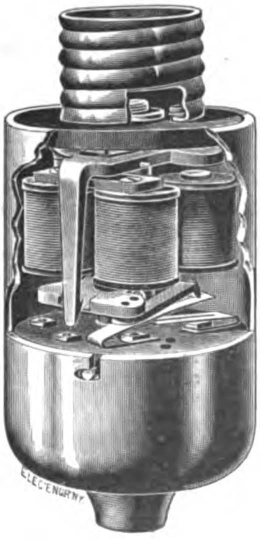


A VERY useful and ingenious little contrivance is the wire and plate gauge shown, full size, in the accompanying illustration. It is intended to be carried on a key ring, and is instantaneous in action, simple in construction, and can neither get out of order readily, nor become inexact. The wire and plate numbers are shown on one side, and on the other appear the diameters in fractions of an inch. The instrument is made of polished steel, and is manufactured by the Rush & Gildemeyer Mfg. Co., 1004 Walnut St., Philadelphia.

DIXON'S GRAPHITE GREASE.

A large manufacturer of steam, hydraulic and hand elevators in Baltimore writes that they have been using Dixon's Graphite grease on their elevators for about two years, and find it superior to any lubricant they have ever used. They also use it on their wire cables to prevent rust, and for the guides of elevators. It is made by the Jos. Dixon Crucible Co., of Jersey City, N. Y.

THE ROUSSEAU AUTOMATIC SOCKET SWITCH.



ROUSSEAU'S AUTOMATIC SOCKET SWITCH.

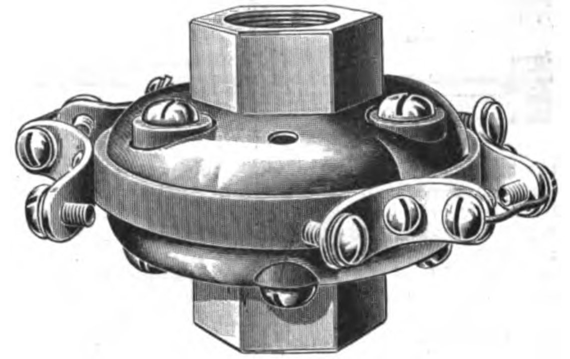
It is frequently desirable to light and extinguish lamps from a distance, and a convenient method of accomplishing this without running heavy wires will find many applications. To accomplish this in a simple manner, the well-known method of employing a pair of push buttons has recently been applied for switching on and off an incandescent lamp, much in the same manner as in connection with automatic gas burners.

The accompanying illustration shows the device as constructed by Mr. D. Rousseau, of this city. As will be seen, the switch of the lamp contains two pairs of electro-magnets, each pair in circuit with a push button. In the position shown, the switch contacts, consisting of two blades of spring copper, are out of contact. By pressing the "lighting" button, the lower armature is attracted and raised, while the arm attached to it presses the springs into contact and thus closes the circuit to the lamp, which lights. The armature thus raised is maintained in position by engaging with a latch attached by an arm to the upper armature.

To extinguish the lamp the other button is pressed, which attracts the upper armature and trips the latch, allowing the lower armature to fall and the springs to break contact. The device is evidently very simple in its nature and can be readily attached to any lamp. It thus enables a lamp to be controlled at any distance by a very fine auxiliary wire without the necessity of carrying the lamp circuit out of its direct course.

STAR ELECTRIX COMBINATION CUT-OUT AND INSULATING JOINT.

THE accompanying engraving illustrates a new device manufactured by the Star Electrix Co., of Philadelphia, consisting of an insulating joint of a particularly strong and convenient type, to which is added a neatly arranged, double-pole cut-out device.



STAR ELECTRIX COMBINATION CUT-OUT AND INSULATING JOINT.

By the use of this combination joint, a separate cut-out at the fixture is dispensed with, and the whole arrangement is covered by the canopy of the fixture. The construction is such that without the brass clips and fuse, it can be used as the ordinary insulating joint.

PHILADELPHIA NOTES.

THE WASHINGTON ELECTRIC CONDUIT CO. are laying five miles of their patent glazed terra-cotta conduit in the city of Washington, D. C. This conduit is being extensively used in the cities of Chicago, Cleveland, Milwaukee and Baltimore.

MR. J. W. PARKER, Philadelphia agent for the Ball Engine Co., has sold a 150 h. p. special railway Ball engine to the Allentown, Pa., Electric Railway Co.; also a 150 h. p. tandem compound special railway engine to the Lebanon, Pa., Electric Light Company.

MR. B. FRANK JOHNSON, general agent for the Interior Conduit and Insulation Co., has contracted, through the Edison General Electric Co., to equip throughout the new Chamberlin Hotel, at Old Point Comfort, with interior conduits.

MR. HENRY B. CUTTER has just installed a 35 Station Eco Magneto watchman's clock system at John B. Stetson's hat factory; also a 35 station clock at the Penn Mutual Building, 925 Chestnut street.

MESSRS. W. H. WESTON & CO., switch manufacturers, are adding more room and new machinery to their factory whereby they will triple their present capacity.

NEW YORK NOTES.

THE "ACME LINK" AND "EUREKA DYNAMO" belts, made by the Page Belting Co., 16 Dey street, New York, are meeting with remarkable success for power transmission in electric lighting and street railway stations. The principles embodied in these belts show greater traction power and strength compared with belts of old style as heretofore constructed. Among recent orders filled by this company was one for the Hampton and Old Point Comfort R. R., at Hampton, Va., where two 20″ wide "Acme" link and several "Eureka Dynamo" belts are running, the superintendent says, "as nicely as any thing I've ever seen."

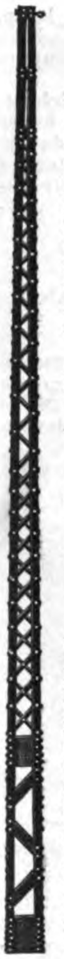
MR. F. SAXELBY will join the forces of Mr. Shain in the Eastern district of the Edison General Co., and while acting as salesman for all the products of the company, will make a specialty of lamps, with which he has had a long experience in their manufacture.

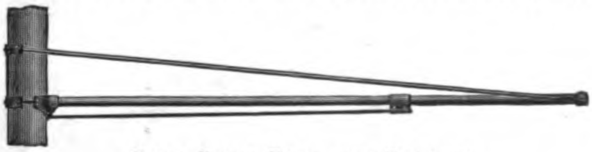
GILES STEEL RAILWAY POLES AND BRACKETS.

THE Giles steel railway pole is made up of four angle sections, forming the four corners of a square, and to resist the pull of the span wire is a simple matter of making these angles of sufficient size and weight to furnish the required cross section. The pole being square, offers as much resistance to pull in one direction as another. At the grade line where the chief trouble has been with many other poles we separate the angles by two large plates. These poles can be set to pull against a stone or other solid packing at this point without danger of crushing. The design of the pole and light, tapering evenly from the ground up and as it is latticed and open it does not present as clumsy an appearance as a solid pole.

In addition to the above points the pole is especially designed for the heavy strains met with in double track and curve work.

The Giles steel railway bracket is of the best lap or butt-welded steel tube held in place against the lower plate of the bracket by a wrought iron clip rivetted to same. This plate is clamped to the pole, no screws or spikes being necessary and is of such size and shape as will allow of ready attachment to poles of different diameters. The load is directly supported by two truss rods of steel, which pass on either side of the pole and are attached to a heavy bar or plate. They are provided with thread or nut, by means of which the height of the arm is adjusted. A smaller rod is run on the under side of the arm, which prevents raising of same by the passing under of the trolley. It is claimed that this is a rigid bracket, free from swaying motion, lifting, or springing and vastly superior to those made wholly or in part of cast iron. They are made of first-class materials in a first-class manner and are fully guaranteed. The above are handled in the West exclusively by the Illinois Electric Material Company, 158 Fifth Avenue, Chicago.

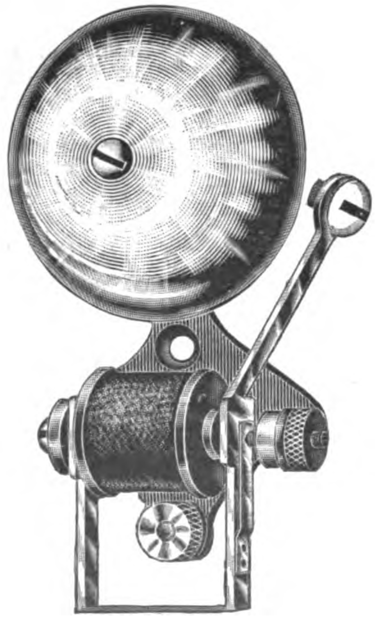




GILES STEEL POLE AND BRACKET.

THE HAY-HORN BELL.

THE accompanying illustration represents the new bell manufactured by Hay-Horn Mfg. Co., of Chicago. This bell is not only attracting attention in this country, but is being used extensively abroad, wherever samples have been tested. The object of the manufacturers in making this style of bell is not only to reduce the cost nearly one-half, but also to give loudness of tone with a small battery current.



THE HAY-HORN BELL.

Much time is generally required in adjusting the hammer of a bell so as to produce the best results, but the manufacturers have overcome this difficulty by introducing an adjustable hammer, enabling one to set it right very quickly. The bell is well made and finished, having platinum contacts and is tested on a circuit of 200 feet, using only one cell of battery.

The Eastern agent of the company is Mr. Jas. H. Mason, 118 Park avenue, Brooklyn.

WESTERN TRADE NOTES.

THE FLETCHER & FLETCHER ELECTRIC CO., 1315 St. Water street, Cleveland, Ohio, are enjoying a boom in their electrical supply business, and are filling orders for their specialties and novelties in all parts of the world. This is a highly encouraging state of affairs, and it is also interesting to note that the outlook was never better.

M. C. CHASE, 43 to 45 S. Canal street, Chicago, the well-known manufacturer of hard rubber goods, is doing an active and increasing business, and reports orders as coming in in a very brisk manner. He manufactures all kinds of articles of hard rubber, and his battery cells and other specialties are widely known and used.

ANDERSON & JOHNSON, 46 S. Canal street, Chicago, are making a large number of their disc exhaust fans, and have recently received orders for a very large amount of business, so that they are running their factory to the full limit of its capacity, to be ready for a heavy demand for their fans which, with the warm season, is now upon them.

WILLIAM BARAGWANATH & SON are constructing a large number of their well-known feed water heaters of various sizes. These are known in electric power and light stations all over the country, for their strength, durability, and thoroughly reliable operations.

THE ELECTRICAL ENGINEERING CO., who are handling the Standard dynamos and the Perret motors, are meeting with large success in the introduction of both of these well-known machines. They are also contractors for the complete equipment of electric light and power plants, and doing a flourishing and prosperous business.

THE GREAT WESTERN SUPPLY CO. report that their new catalogue of railway supplies is now in the printer's hands and will be ready in about two weeks. It will be very complete, covering all the standard appliances required in the construction of electric railway lines, of the different systems, and in addition, all their own specialties.

THE ELECTRIC MERCHANDISE CO., of Chicago, has issued birthday cards celebrating its first anniversary under its present management. It has had a brilliant career, not due to luck, but the outcome solely of hard work and sound judgment in meeting the demands of a new industry.

THE ELECTRICAL SUPPLY CO. has put on the market a line of aluminum shades for incandescent lamps. They are spun in one piece, and can be had frosted or in mottle finish, and bright satin finish inside. They do not tarnish, and can be cleaned by simply wiping them off with a damp cloth or chamois.

THE THOMSON-HOUSTON ELECTRIC CO. reports the following recent sales made through its Western isolated lighting department: Smith Steam Baking Co., Kansas City, Mo., 50 light incandescent plant; Wainwright Real Estate Co., St. Louis, Mo., 3,000 incandescent lights; Iowa Agricultural College, Ames, Ia., 6 arc light dynamo, 35 light incandescent dynamo, one 1. h. p. motor, and appurtenances for laboratory use; Cudahy Packing Co., Sheffield & North aves., Chicago, 125 incandescent lights; Carson, Pirie, Scott & Co., Adams & Franklin streets, Chicago, 35 arc light and 400 light incandescent plants; S. S. Badger, Ouray, Col., 100 incandescent light plant; Central Market Co., State & South Water streets, Chicago, 18 arc light plant and 200 light incandescent plant; Chicago City Railway Co.. 150 light incandescent plant; H. H. Shufeldt & Co., 23 Larabee street, Chicago; 250 light incondescent dynamo to increase capacity of plant sold last November.

THE EMERSON ELECTRIC MANUFACTURING CO., of St. Louis, has issued a neat circular relative to its new Weston alternating current motor, recently illustrated and described in THE ELECTRICAL ENGINEER.

THE
Electrical Engineer.

VOL. XI. JUNE 17, 1891. No. 163.

PINOLET'S ANNUNCIATOR SYSTEM.

IN the hotel and house annunciators at present employed, it is necessary after a call has been noted to reset the drop by hand, and when this is not done immediately a second or third drop may fall and thus make it impossible to know whether the first call has been repeated. It is therefore necessary that the attendant be constantly engaged in resetting the drops, so as to avoid confusion. Again, the bell usually sounded at the time the drop falls, rings only for an instant, and frequently fails to attract the attention of the clerk, who is usually engaged in other duties at the hotel desk. To obviate both these difficulties, Mr. Louis M. Pinolet, of Brooklyn, N. Y., has devised an ingenious annunciator system, without adding any additional complications, or increasing the amount of wiring necessary about the building.

The accompanying engravings, Figs. 1, 2 and 3, show the annunciator in plan, and two sectional views, respectively, and Fig. 4 is a diagram of the circuits employed.

It will be noted that digits are marked upon concentric transparent dics, *m'* and *m*, which are rotated by a pawl and ratchet electric motor, and that each disc stops independently of the other at the proper place to give an indication. The means for stopping any given disc, consists of an armature *r* adapted to be attracted into the path of a projection *p*, *p'* or *o*, *o'* upon the disc.

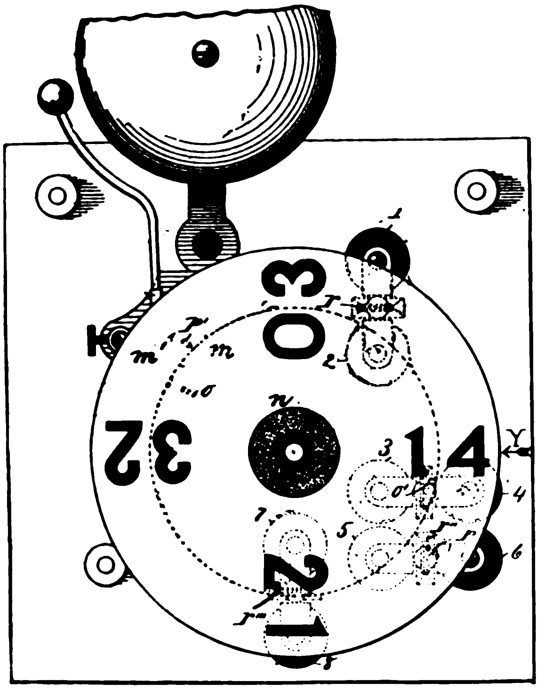

FIG. 1.—PINOLET'S ANNUNCIATOR SYSTEM.

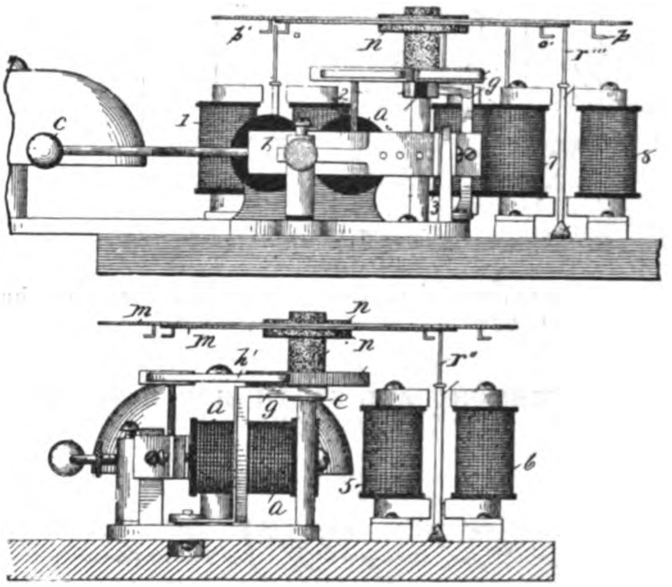
The magnets for attracting the armatures are arranged at proper distances around the axis of the discs, which rotate, when the motor is in operation, on account of the friction between them and washers *n* on the motor, until one of the discs is stopped by an attracted armature. The motor continues to turn the other disc until it is likewise stopped, and then continues its motion until the ratchet wheel has made a complete rotation. In the engraving these magnets are the smaller ones, while the single large magnet *a* is for operating the bell and motor.

When a push button *v*, in any room, is pressed, a current passes through the bell magnet, whose armature vibrates in the usual manner, and rotates the ratchet wheel of the motor, the arbor of which carries a piece of insulation normally in contact with the brush *g*. By the time the pressure is removed from the push button, the insulation has left the brush, thereby closing a local circuit which rings the bell until the insulation has passed around once, when it interrupts the local circuit, and the bell ceases to operate. At the same time in which the button is pressed, one of the magnets 1, 2, 5, 6 and one of 3, 4, 7, 8 are included in the circuit, and attract their armatures, which must evidently be held until the motor stops. For this reason, these magnets are introduced into the local circuit by means of circuit closers which make contact with the attracted armatures.



FIGS. 2 AND 3.—PINOLET'S ANNUNCIATOR SYSTEM.

It is quite surprising to notice in the operation of the device, that instantly removing the finger from the button that has been pressed, does not prevent the working of the instrument, the time occupied in indicating a number being two or three seconds, while the bell rings for six or seven seconds.

As the indicating numbers are formed by the combination of the digits on one disc with those on the other, it is evident that the number of signals which can be given is equal to the product of the digits on one disc by those on the other, thus requiring fewer magnets and rendering the construction proportionally simpler than that of an ordinary annunciator. For example, if a hotel has 50 rooms, its annunciator would have only 15 magnets, besides the bell magnet, there being five digits on one disc and ten on the other. It is a peculiar property of the device that it requires no setting, the last indication remaining till another is given. In practice, the instrument has a face plate with an opening opposite the arrow Y for the appearance of the indicating number.

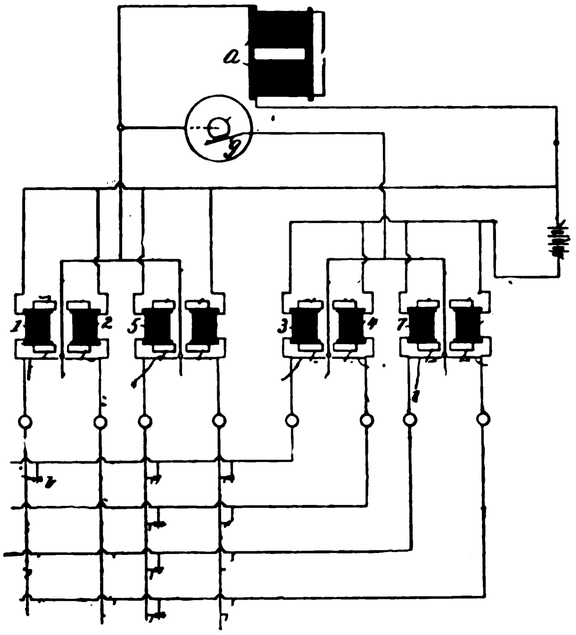


FIG. 4—PINOLET'S ANNUNCIATOR SYSTEM.

THE RICHMOND AND SOUTH SIDE ELECTRIC RAILWAY.

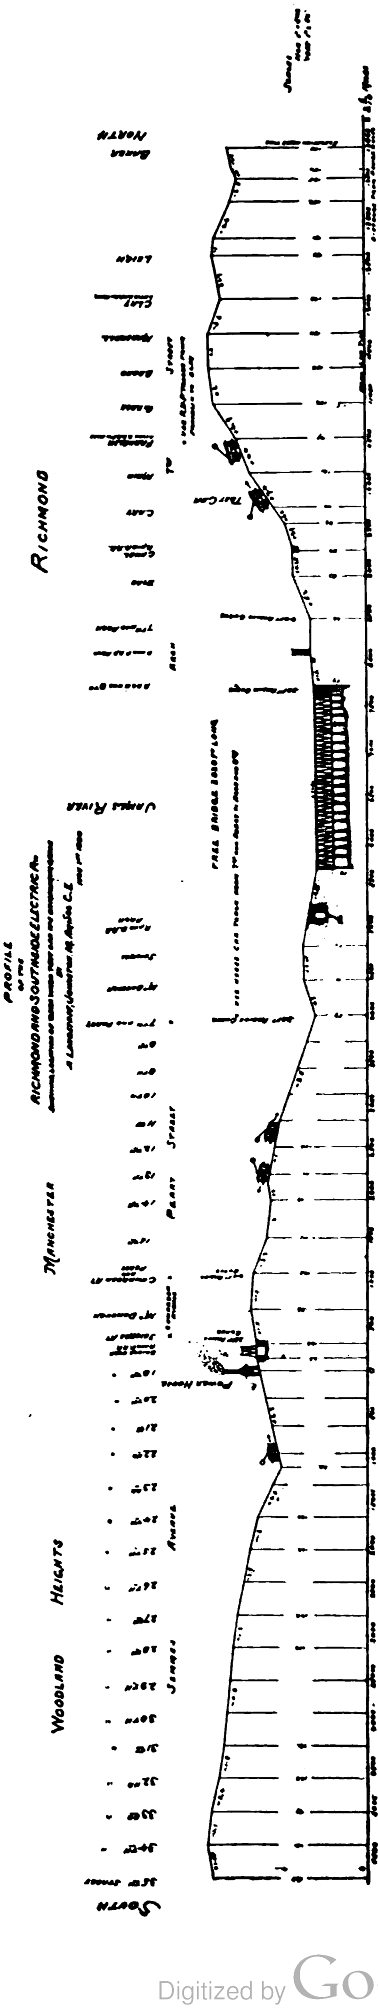
BY

A. Langstaff Johnston

IMMEDIATELY upon the completion of the Richmond and South Side Electric Railway, at Richmond, Va., in October, 1890, the usual tests with the voltmeter and ammeter were made on one car; at the same time the locations of the other four cars (there are five) were taken by observers on them, so that their positions were known when the test car was upon the maximum grade which is $7\frac{4}{10}$ per cent. The tracks were new, curves unworn, and equipment stiff.

The accompanying profile shows the rate and frequency of the grades and curves, the minimum of the latter being 30 foot radius. The accompanying table, in connection with the profile, explains fully the test. The length of the road is four and a half ($4\frac{1}{2}$) miles; although the test was made on $3\frac{7}{10}$ miles only. The road is double track, laid with the following kinds of rails: From the northern terminus to 7th and Clay streets, 45 lb. side bearing steel tram rail; at this point it connects with and passes over the Union Passenger Railway (the first electric railway built here, and on which the Sprague motor was developed) for four blocks to 7th and Franklin streets. From this point to Free Bridge is laid with a 50 lb. steel grooved rail on a 5"x8" pine stringer.

At the Free Bridge connection is made with the Manchester horse car tracks, belonging to the Richmond and South Side Railway; these tracks are 45 lb. iron side bearing tram rails which were bonded on the bridge for the electric road. From the south end of the bridge to 7th and Perry streets, 35 lb. Johnson girder rail was used, which had to be strengthened and trussed before it would



PROFILE OF THE RICHMOND AND SOUTHSIDE ELECTRIC RAILWAY, WITH CARS IN OPERATION AT DIFFERENT POINTS.

stand the traffic of electric cars. From 7th and Perry streets to Woodland Heights 30 lb. T-rail, on cross ties, is used.

The equipment consists of five 16 ft. vestibule Brill cars, with two 15 h. p. Sprague-Edison motors. At the time of test, current was furnished by one 80,000 watt Edison dynamo, driven by a 100 h. p. Ball engine. The gearing employed on the motors is Atwood's noiseless wooden tooth, which gives great satisfaction. The table shows in a striking manner the increase of power required at curves and grades and also the influence of the type of rail employed.

RECORD OF A TEST MADE OVER THE LINE OF THE RICHMOND AND SOUTHSIDE ELECTRIC RAILWAY, BY A. LANGSTAFF JOHNSTON, C. E. CHIEF ENGINEER, NOV. 1ST, 1890.

Instruments placed on Car No. 5, and Car run over the east track from the south end at 34th street and Semmes avenue, Woodland Heights, to 7th and Baker street, Richmond.

The road has now been in operation for seven months. The electrical repairs have been so remarkably low that the management considers them almost nothing.

ELEMENTARY GEOMETRICAL THEORY OF THE ALTERNATE-CURRENT TRANSFORMER.—III.

BY

Chas. Steinmetz.

Now this secondary M. M. F., l_1 combines with the (still unknown) M. M. F., L, of the primary current to the resulting M. M. F., $F = 2{,}400$ ampere turns. But the combination of sine waves in their polar co-ordinate system follows the fundamental law of the *parallelogram* of forces, that is, Fig. 4:

"Any two sine waves, in phase and intensity (amplitude) represented in polar co-ordinates by straight lines, $\overline{OB}$, $\overline{OC}$, *combine to a resulting wave* $\overline{OD}$, *which, in its phase and intensity, is represented by the diagonal of the parallelogram, which has the two component waves* $\overline{OB}$ *and* $\overline{OC}$ *as sides."*

For, in Fig. 4, the (algebraic) sum of the two projections $\overline{ob}$ and $\overline{oc}$ of the component waves, $\overline{OB}$ and $\overline{OC}$ upon any radius, $\overline{ox}$ is equal to the projection $\overline{od}$ of the resulting wave, $\overline{OD}$ upon $\overline{ox}$, because $\overline{oc} = \overline{bd}$.

From this follows directly the *law of the polygon of sine-waves.* This, or rather a similar form of a parallelogram law for sine waves, has been used before by Kapp, Blakesley and others, but, I hardly think, with a full appreciation of its convenience in dealing with alternate current phenomena.

In reality, the parallelogram law is nothing but the geometrical formulation of the *law of conservation of energy.* Hence the parallelogram law appears in combining velocities, accelerations, forces, rotary movements, electric and magnetic waves, etc.

At the same time this law, together with the fact, that all the differential and integral functions of sine functions are sine functions again, gives the proof that, if the primary E. M. F. of the transformer is a sine wave, all the other electric and magnetic quantities are sine waves also.[1]

By using this parallelogram law, we now get the primary M. M. F.,

$$\overline{OL} = L, \text{ Figs. 2 and 3,}$$

as the second side of a parallelogram, of which the *secondary* M. M. F., $\overline{OL_1}$ is one side, the *resulting* M. M. F., $\overline{OF}$ the diagonal.

In Fig. 3, we have practically the same diagram as in Fig. 2, repeated, except that the circles are left out, because they are needed only when dealing with the instantaneous values of the electric and magnetic quantities; while, when only considering their mutual combinations and correlations, these sine waves may be represented in phase and strength (amplitude) by their maximum values, as shown in Fig. 3.

Measuring $\overline{OL}$ in the parallelogram, OL_1, FL, we get the *primary* M. M. F. determined by:

$$\overline{OL} = 1.152 \text{ inch,}$$

$$\text{angle } AOL = \varphi = 38.7 \text{ degrees.}$$

---

[1] *Hysteresis* will be treated of later on.

Hence the maximum M. M. F. of the primary current is :

$$L = 3{,}840 \text{ ampere turns,}$$

since 1 ampere turn = .0003 inch,
and occurs at an angle of : $\varphi = 38.7$ degrees,
that is, at the time,

$$t = \varphi \frac{T}{2\pi} = .0008 \text{ second,}$$

after the zero value of the resulting M. M. F., F.

The circle with $\overline{oL} = 1.152$ inch as a diameter, cuts out on any ray $\overline{ox}$ (Fig. 2), the instantaneous value of the primary M. M. F., for instance for $t = \frac{T}{6}$, $\vartheta = 60°$;

$$\overline{o\,l} = 1.072 \text{ inch} = 3{,}576 \text{ ampere turns.}$$

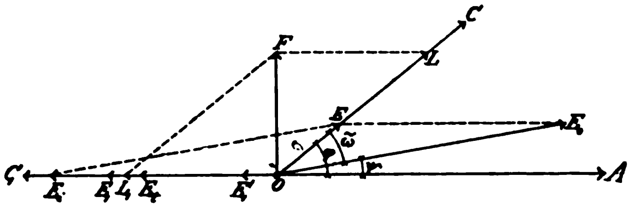

FIG. 3.

The number of primary turns being $n = 80$, the maximum value of the *primary current* is :

$$C = \frac{L}{n} = 48 \text{ amperes ;}$$

hence its *effective value* is :

$$\frac{C}{\sqrt{2}} = 34 \text{ amperes effective.}^1$$

This primary current being represented by the circle having $\overline{o\,c} = 1.44$ inch,

as a diameter, gives for the time, $t = \frac{T}{6}$, the instantaneous value : $\overline{o\,c} = 1.34$ inch = 44.7 amperes.

Let the *resistance of the primary circuit* $R = 1$ ohm ; then the *resulting or heating* E. M. F., that is, that E. M. F., which is consumed by forcing the primary current through the primary resistance, is :

$E = C \times R = 48$ volts, and is equiphased with the primary current.

Therefore it is represented in the diagram, Fig. 2, by the circle with $\overline{o\,E} = .48$ inch as a diameter.

Now this E. M. F., E, is the *resultant* of the *impressed primary* E. M. F. (terminal-pressure, E. M. F. of the dynamo-generator, or potential difference between those two points of the primary circuit, between which the resistance $R =$ 1 ohm), and the E. M. F. *induced* in the primary coil of the transformer by its varying magnetism.

This *induced primary* E. M. F. has the maximum value :

$$E_1 = \frac{2\,\pi\,n\,M}{T} = \frac{n}{n_1}\,E_1 = 133 \text{ volts,}$$

at the same time as the induced secondary E. M. F., E_1 ; that is, at the time $t = \frac{T}{2}$, or the angle, $\vartheta = 180°$. Hence it is represented by a circle with $\overline{o\,E_1} = 1.33$ inch as a diameter.

From the *resulting* E. M. F., E, and the *induced primary* E. M. F., E_1, we derive the *impressed primary* E. M. F., E_0 by the parallelogram of sine waves.

The *resulting* E. M. F., E, is the *diagonal* of the parallelogram, the two *sides* of which are the *induced* E. M. F., E_1, and the *impressed* E. M. F., E_0. This parallelogram, $o\,E\,E\,E_0$ gives :

$\overline{o\,E_0} = 1.73$ inch, that is : $E_0 = 173$ volts as the *maximum impressed primary* E. M. F., which occurs at an angle $A\,o\,E_0 = \psi = 10.0$ degrees :
that is, at the time $t = .0002$ seconds.

Hence the *effective value of the impressed primary* E. M. F. is :

$$\frac{E_0}{\sqrt{2}} = 122 \text{ volts effective,}$$

and the *shifting of phase* between primary current and impressed E. M. F.:
angle $\omega = \varphi - \psi = 28.7$ degrees, or about .0006 second.

At the time, $t = \frac{T}{6}$, the impressed primary E. M. F. has the instantaneous value :

$$e_0 = \overline{O\,e_0} = 1.11 \text{ inch} = 111 \text{ volts.}$$

The difference of phase between impressed primary E. M. F., and secondary E. M. F. is, angle $180 - \psi = 170°$.

Between primary and secondary current, angle $180 - \varphi = 141.3°$.[1]

Quite frequently the size of the primary E. M. F. and of the secondary E. M. F. in commercial transformers is so different, that we are obliged to use different scales for the primary and for the secondary circuit. For instance in a transformer, which yields 100 volts in the secondary circuit, when the primary coil is fed by 1,000 volts, we may represent.

In the *secondary* circuit :

1 volt = .01 inch.	1 ampere = .03 inch.

In the *primary* circuit :

1 volt = .001 inch.	1 ampere = .3 inch.

M. M. F. and effect are always represented in the same scale in both circuits.

Let $R_1 = .4$ ohm be the internal resistance of the secondary circuit, then the maximum *drop of potential in the secondary* for full load is :

$$E_1^{\,1} = R_1 \times C_1 = .4 \times 50 = 20 \text{ volts,}$$

represented by the circle over, with $\overline{o\,E^1_1} = .2$ inch as a diameter.

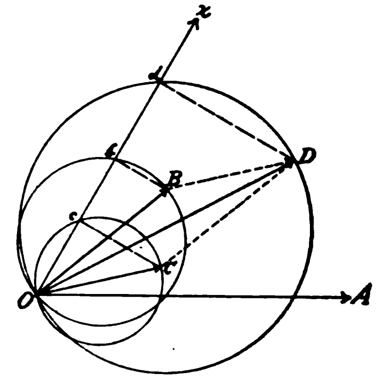

FIG. 4.

The *maximum terminal pressure of the secondary* for full load is :

$E_1 = E_1 - E_1^{\,1} = 100 - 20 = 80$ volts, and is represented by the circle, with

$\overline{o\,E_1} = .8$ inch as a diameter. Hence its *effective value* is:

$$\frac{E_1}{\sqrt{2}} = 56.5 \text{ volts effective.}$$

It is of interest to note, that primary current and secondary current are most of the time flowing in opposite direc-

---

1. This figure is considerably larger than : $\frac{n_1}{n}\,C_{1\,\text{eff.}} = \frac{60}{80} \times 35.35 = 26.5$ amperes, assumed in the first approximation ; but only because of the very unfavorable constants chosen ; in reality the primary current for full load is very nearly $\frac{n_1}{n}\,C_1$ in good transformers, so that for laying out the size of the wires it can be assumed as equal to $\frac{n_1}{n}\,C_1$.

[1] In well built commercial transformers, ω is considerably smaller, being for full load sometimes less than one degree, and angle $180° - \psi$ and angle $180° - \phi$ differ hardly perceptibly from 180°.

tion, and have the same direction only twice during each period, for angles between 90° and $90° + \varphi = 128.7°$; and 270° and $270° + \varphi = 308.7°$.

Impressed primary and secondary E. M. F. are of the same direction only twice per period for 10 degrees, for angles between 90° and $90° + \psi = 100°$; and 270° and $270° + \psi = 280°$.

Primary current and primary impressed E. M. F. have opposite directions, that is, the transformer sends back energy into the main-line, twice per period during 28.7°, for angles between:

$$90° + \psi = 100° \text{ and } 90° + \varphi = 128.7°; \text{ and } 270° + \psi = 280° \text{ and } 270° + \varphi = 308.7°.$$

In reality, in closed-circuit transformers φ and ψ are usually very much smaller than assumed here.

Thus all the phenomena met with in a transformer acted upon by sine-waves can be produced in the polar-diagram graphically by circles. Actual data of some commercial transformers will be given in a later chapter.

CENTRAL STATION MANAGEMENT AND FINANCE.—VII.

REPORTS.

BLANK No. 18.—SUMMARY OF INCOME ACCOUNT.

The first three divisions are taken directly from pay-rolls; the next is from the Storekeeper's Report, No. 13, of supplies issued for operating, and the last two divisions are filled in by the clerk from office data. The first column for figures is for the amount or value of the individual items, the second column for all those items which are common expense to all departments of out-put, such as coal, water, cylinder oil, superintendence, &c.

The third column is for such items as are used for arc expense only, including trimmers, carbons, globes, &c.; the fourth is for incandescent expense, like lamp breakage, inspector, &c., and the fifth column for motor expense only, including brushes and other supplies used expressly and exclusively for that purpose.

BLANK No. 17.—SUMMARY OF OPERATING EXPENSES.

The footing of the second column of "common to all" is divided among the columns three, four and five in proportion to the amount of the weekly or periodical out-put of each class, all, of course, being reduced to a common base unit, say, equivalent to full arc lamp hours. The total footing of these last three columns thus gives the total cost of producing the number of units of out-put of each class, and, by division, the cost per unit of the same.

In the average station, such as is considered throughout in these reports, it will be found most convenient to take the arc lamp of the class used therein for a base unit and reduce all other out-put to that unit by comparing the number of watts used by each. Motors are somewhat more difficult of calculation, but taking one h. p. of motor as equal to one full arc lamp will be found nearly correct, as the motors are seldom run regularly up to full power.

In calculating costs by the above method, it will be noticed that actual count is taken in all arc lamp work, whereas the ampere record is taken for out-put from the incandescent circuits. The two classes of service are so entirely different that it is quite difficult to bring them closely into line on any fair basis, and as the loss on arc wire service is comparatively small and constant, and as the same is varying constantly with the load on incandescent service, it is thought to be the best way to take the surest points of both. As a matter of fact, the calculation of costs must be made comparatively, and if cost is figured on out-put at the switch-board, and income is figured on the same basis, the comparison for profit is the same as if it be figured on, say, the total number of lamps wired. Again, in figuring for costs per incandescent lamp wired, and income for the same, it would hardly be fair to compare a station which kept current on only during a short period, with one running 24 hours a day.

To accompany the expense account Form 18 is made to show the income account for the same base units, and all data for unit costs is written in on this blank. The clerk can fill out this sheet mostly from office data, and can also do all the calculating.

THE PHONOGRAPH IN BUSINESS.

BY

F. R. Colvin

It is unfortunate that the phonograph is regarded by the public—particularly by the commercial part of it—as only a wonderful toy, furnishing an evening's entertainment under skillful manipulation, though lately having risen to the utility of a "nickel-in-the-slot" machine. With this opinion prevailing, it is difficult to make the average business man believe that with an hour's practice he can make the phonograph a simple, reliable and indispensable adjunct to his office equipment. It is interesting to note that when the nature of the phonograph was first known, prediction was at once made that stenography would succumb to the machine; on the contrary, the phonograph has come to be the stenographer's best friend. Returning from the court room or lecture at any hour of the day or night, he can easily dictate his notes into it at a speed of 250 words per minute, and have a dozen typewriters, if necessary, simultaneously transcribing them the next morning before he has made his appearance at his office, or while working on another case.

My purpose is, however, to indicate the true function of the phonograph in daily business use as impressed upon me by my acquaintance with this acquisition in the office of The Electrical Engineer. We do not use it in lieu of, but in connection with, the stenographer. During the last hour of each day, our phonograph receives dictation for transcription early the following morning. The cylinders accumulating from this dictation are transcribed while the mail is being opened and distributed, and before it is time for the regular dictation of the day's mail to begin. The distinctive advantage in the use of the phonograph in letter dictation is that the simultaneous presence and work of two persons are not necessary. One wishes to rush off certain matter and leave the office for an hour—no stenographer is immediately available; Miss A. may be receiving dictation; Miss B. may be preparing something for the editorial department that must be ready by a given time; Miss C. may be out at lunch. The phonograph, however, is always ready—a cylinder is quickly adjusted and the matter dictated, a note being left in the office to the effect that cylinders Nos. 1, 2, 3, 4 and 5 are to be transcribed and the letters must be ready by 5 p. m. On returning to the office the letters are ready, awaiting signature. It frequently happens that manuscript must be copied at once and sent away; it sometimes occurs that important work has to be suspended to admit of such copying. A man brings something into our office of which we wish a copy and says, "You could have a copy only I haven't time to wait—I must take it with me." We ask him if he can wait while we read it. "Yes," he says. "All right, we will read it aloud into the phonograph." This being done, our friend may leave with his precious paper at pleasure, and the matter may be copied off from the machine the next day or the next week—whenever most convenient. How often it happens that a manager thinks of a letter which should be written at once, but which waits over until the next day or perhaps is never written, simply because no stenographer is conveniently available at the time; he may make a note to write the letter and lose the note or tear it up upon second thought. It is unnecessary to point out the value of the phonograph in this connection in petrifying and preserving impulse. It is, perhaps, true that phonographs have been placed on trial in some business offices and returned to the company with the verdict of "failure." The verdict was, no doubt, a just one; but it was not "failure" of the machine, it was "failure" of the man. Speech will not come out of a phonograph more clearly than it goes in. One should spell out queer proper names and unusual words just as he would to his stenographer in ordinary dictation. He should speak moderately loud and remember that he is talking to a machine that is a merciless critic and a truthful one whose motives cannot be impugned.

Simple routine letters, such as those of acknowledgment and the great mass of short letters we all handle from day to day, can be rattled off into the phonograph with short practice; but there are few people living who can compose a smooth letter of considerable length and dictate it continuously into the machine without hesitation. A feeling of solitary stage fright comes over one at first which takes time to dispel; in the presence of this eternal echo one hears his imperfect self, recognizes his shortcomings of diction and ought to be frightened. It is well, then, to make a skeleton, either on paper or in the mind, of longer letters and then read them into the phonograph as rapidly as is desired.

The phonograph is, therefore, a great doctor for the hesitating dictator who has not digested what he intends to say. This dyspepsia of dictation however readily yields to the pepsin of practice and the pancreatin of persistence. The phonograph also makes itself felt in our office on the occasion of the impending absence from the city of the manager. A larger number of cylinders is "loaded up" on such an occasion than usual, to be written out at leisure during the next day or two. This particular use of the machine might be availed of in the case of The Electrical Engineer to a greater extent, were it not for the simultaneous use made of the long distance telephone, which keeps the phonograph busy even in the absence of the writer. Whether I am in Philadelphia, Washington or Baltimore, in Erie or Buffalo, in Rochester or Boston, the morning mail is read to me over the long distance telephone from New York by one of our stenographers, and the answers taken down in short hand at the New York end of the wire. Ten minutes after I hang up the telephone in Buffalo or Washington, the stenographer is reading his "overflow" notes into the phonograph for distribution, and the mail dictated over a wire from two to five hundred miles long in the morning, goes out of our office in the evening just as though I had been there all day. This is not a dream or a future possibility; it is what is done in this office as frequently as absence makes it necessary, and what many more houses are doing from day to day as the advantages of modern electrical facilities are more appreciated and understood.

For the benefit of those more or less unfamiliar with the phonograph, I would say that there are three sources of power in use, any one of which is suitable for the propulsion of the phonograph motor. First, electric light mains ; second, storage batteries ; third, primary batteries of great length of life and absolute constancy. Where power is derived from the electric light mains, a specially wound motor is furnished. The use of the phonograph on a large scale probably most nearly approaches perfection in one of the large electrical offices where no fewer than 30 of these instruments are inconstant daily operation. Here heads of different departments and their assistants dictate all their mail into phonographs alongside their desks and send the loaded cylinders to the phonograph room of their department to be transcribed by one of half a dozen or more typewriters, who also are provided with phonographs on which cylinders are placed and worked off as soon as received. The cylinders are then sent to another phonograph, which is kept busy all day shaving them, after which they are returned for use again. The question is always asked: "How much do these cylinders cost, how many letters will they take apiece, and what do you do with them after using?" They cost 20 cents apiece, will receive easily from six to ten letters of less than a page length, are furnished promptly by the phonograph company either on written or telephonic order. They are shaved by simply setting a little knife or plane and turning on the current. In my office the tonsorial part is satisfactorily presided over by an office boy, so it will be seen the process does not involve the intricate. A dozen cylinders shaved once a day will take care of a good sized correspondence of from fifty to one hundred letters per day, according to their length and the practice of the operator. The yearly rental of the phonograph alone is $40. Where a primary battery is provided and kept charged by the company, the rental is $55. Where current from the mains is used, one pays $40 per year for the machine and settles with the electric light company for the current used as per meter. This is the best and cheapest way.

The day is, I believe, coming, when fifty out of one hundred offices having typewriting machines will use this instrument, and when the veil of mystery will no longer conceal in its voluminous folds the true uses and possibilities of the Edison Phonograph.

THE THOMSON RECORDING WATTMETER.

THE announcement made in our columns last week that Prof. Elihu Thomson had been awarded the first prize,[1] for his recording wattmeter in the Paris Meter Competition, has, it seems, created widespread interest and satisfaction in electrical circles, and we have received numerous communications requesting further information regarding the construction and operation of the instrument tested at Paris. The meter in question was described in our issue of November 5, 1890, but it may not be amiss to recall briefly its salient features, and to add some further information regarding its use in practice.

The conditions which Prof. Thomson set out to fulfill in his meter were as follows : 1. It should register the watt-hours ; that is, the summation of *energy*, and not of current, delivered to any circuit. 2. It should be adaptable for either continuous or alternating circuits. 3. There should be accuracy throughout the entire range of the instrument. 4. The instrument, so far as possible, should give direct readings, and all constants for sake of simplicity avoided. 5. The instrument should combine simplicity of design and parts with noiselessness and durability.

All these conditions have been met in the meter which is illustated in the accompanying engraving, Fig. 1. As will be seen, it consists of a vertical shaft resting in a jewelled bearing below, and, guided by an upper bearing, carries on its upper part a hollow frame wound with a set of coils, forming a sort of Siemens armature of polygonal outline without any iron core. The coils of the armature are attached to a commutator carried on the shaft near its upper bearing, the commutator being made of a little larger diameter than the shaft on which it is placed, and is of special construction both as to material and mounting of its parts. Two light springs bear upon the commutator and constitute the commutator brushes. The armature coils are wound with fine wire and in circuit with the armature is placed a non-inductive resistance, carried in the frame at the back of the meter.

The armature coils have placed adjacent to, and surrounding them, a set of fixed coils, generally made without iron, through which coils the main current to be measured passes. They furnish an air field of greater or less strength according to the current flowing in the coils. An endless screw on the shaft engages with a wheel in the registry train whereby the rotations of the armature are recorded.

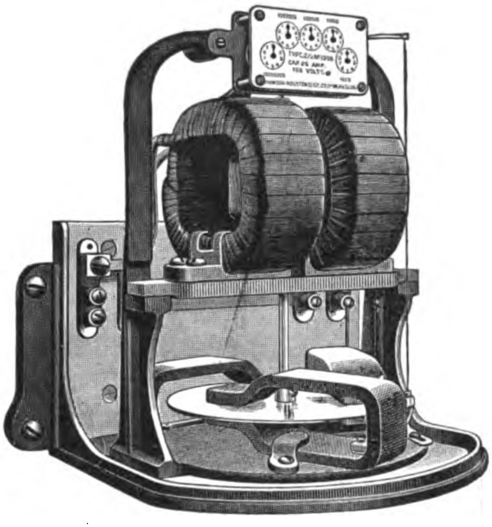

FIG. 1.—THE THOMSON RECORDING WATTMETER.

On the lower part of the shaft which bears the armature is mounted a copper disc the plane of which is at right angles to the length of the shaft, and which rotates with the shaft. This copper disc moves between the poles of a number of permanent magnets which are placed so as to embrace it.

The principle of action is quite simple. The amount of load or retardation obtained by the copper disc moving in the magnetic field is directly dependent on the speed, and the retarding effect may be said to vanish when the motor stops, and to increase regularly as the speed increases. In like manner the torque or turning force exerted by the armature may be said to vanish when the field current becomes nil, or when there is no load, and to increase regularly under constant potential between the mains as the load of lamps, or other working devices, is increased, that is, as the current passing through the stationary field coils increases. The result of this is that the speed of the meter shaft increases in strict proportion to the load so that the registry is uniform throughout the range, except with the very smallest loads.

The meter which is applicable to both direct and alternating current circuits registers the energy in watt hours, which can be read directly off the dials.

It has been found from tables that have been carefully calculated, that an incandescent lamp consuming 1,000 watt-hours of electrical energy will give about one-tenth of the illumination given by 1,000 feet of gas under ordinary circumstances ; consequently, in order that the customer may pay for electric light at the same proportionate rate for the same illumination that he has been paying for gas, the price per thousand watt-hours of electricity can be placed at one-tenth of the price per thousand feet of gas. This permits of a ready method of calculating the charges from the meter readings, and this computation is done practically automatically by the use of the chart illustrated in Fig. 2. In this chart, dollars and cents are read off on the vertical line on the left, while the horizontal line at the bottom indicates thousands of watt-hours. The diagonals indicate the lines to be taken as reference, depending upon the price charged per 1,000 watts, which, of course, varies in different localities.

---

[1] The first prize was awarded jointly to Prof. Thomson and Prof. Aron, for their respective meters.

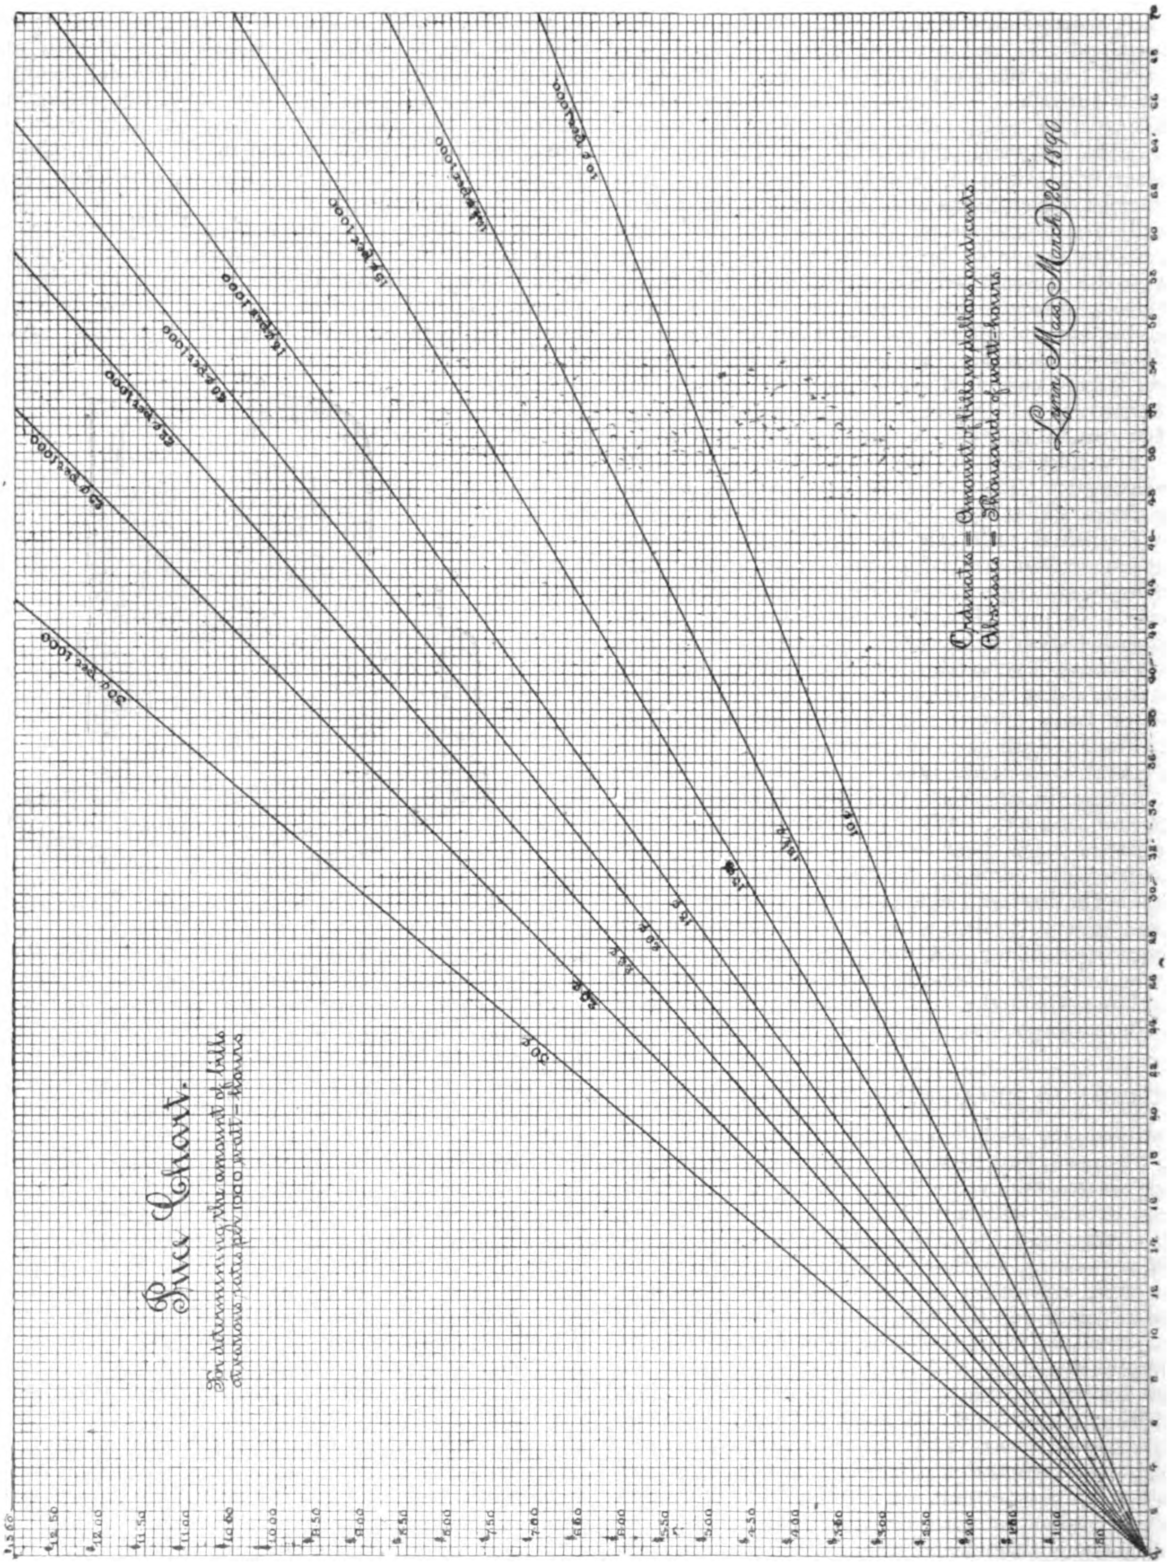

Fig. 2.—Chart For Computing Thomson Meter Charges.

We may add that though but a few months have elapsed since Prof. Thomson submitted his successful meter to the Paris Testing Committee, a number of improvements have been introduced which add still more to its value.

THE PROTECTION OF BUILDINGS FROM LIGHTNING.

BY

C. J. Hubbell

I NOTICE, among the Transactions of the American Institute of Electrical Engineers at a special meeting held April 21, 1891, a paper was read by Mr. N. D. C. Hodges, "On Possible Modifications in the Methods of Protecting Buildings from Lightning," which provoked considerable discussion among the members present, and during which my name, as "a well-known lightning rod manufacturer," was mentioned by Mr. Edward P. Thompson in connection with a series of experiments.

I would like to say a few words in answer to Mr. Hodges' theory, that a dissipated conductor protects. He asserts, moreover, that there is no instance on record where a dissipated conductor has failed to protect. It is a well-known physical law, that can be readily proved to the satisfaction of any intelligent person, that the earth is a permanent magnet, and the rendezvous of all thunder storms. When a cloud, charged with a given kind of electricity, approaches the earth, the latter, that is the subterranean sheet, or permanent moisture belt, becomes charged with an electricity of an opposite polarity. The two electricities attract each other; the electricity of the earth precipitates itself upon the lines of least resistance, gathering up in increasing intensity to the higher points under the attraction of the storm cloud, until sufficient potential has accumulated to overcome the resistance of the dielectric, when a discharge takes place and the equilibrium is restored.

There are more, what is commonly called, "upward strokes" than "downward" ones, and more disasters have occurred from the former than from the latter. Yet Mr. Hodges ignores the earth connection entirely, without even resorting to the method of Clerk Maxwell by insulating the building from the earth. I might say to Mr. Hodges, with more truth than is contained in his assertion, namely, "that there is no instance where a dissipated conductor failed to protect," that there is no instance on record where a well ordered and properly constructed lightning conductor of sufficient capacity and good and intimate connection with the subterranean water bed or permanent moisture belt, failed to protect.

I herewith submit a few well authenticated instances where a dissipated conductor failed to protect. Anderson, in his well-known and standard work on "Lightning Conductors," contains the following passages bearing directly on this subject:

Page 315. Date, July 21, 1745. Tower of Monastery of Bologna. Result: Shattered. Lightning followed conductor and *melted it.*[1] Authority, Reivnarus Bl. 93.

Page 315. May 31, 1748. Top of a church tower, Witzendorf, shattered and tore off the roof. *Melted the conductor.* Authority, *Hamburg Magazine*, IX., 301.

June 16, 1754. Belfry of Newbury Church damaged, point of spire shattered and other damage. *Conductor melted.*

Page 186. Prof. Landriani, of Milan, draws attention to the paramount importance of a perfect earth connection.

Page 312, same authority. On Trinity Sunday, June 8, 1879, a violent thunderstorm broke over the town of Arxham about half-past three in the afternoon, and the spire of St. Mark's Church was struck by lightning. A Sunday-school class was being held in the room at the base of the spire and the teacher and five of the scholars were burnt. Some of the stone work of the spire was also displaced and thrown down. Cause: A copper conductor of too small capacity and the earth connection not adequate.

Many more instances could be given in addition to the above.

Referring to the article in the London *Electrical Review*, quoted by Mr. Hodges, in which it is said that lightning does not play as destructive a part as it did forty or fifty years ago, and that even those ships unprovided with conductors had suffered less damage than a smaller number of ships experienced formerly, etc., I reply, that the reason that modern vessels are less frequently injured by lightning than formerly, is because of the fact that more vessels are now built of iron, and the still more important reason that wire rigging instead of rope, as formerly, is almost universally used, while, in addition, the masts of many vessels are of iron and hollow. I could cover many pages with what should be accepted as strong evidence for the necessity of a good earth connection and a refutation of what I cannot but regard as a very unscientific statement based upon no valid reasoning, that a dissipated conductor protects. Certainly Mr. Hodges, with his strip of copper 75 feet to the pound, placed as an offering to the insatiate monster in order to protect the structure, magazine, etc., it is tacked on to, has but a very small conception of the potentiality of a discharge of lightning whose disruptive powers are such as to hurl tons of granite from their foundation as if they were but feathers, so that it may take the path of least resistance, to the water which it was seeking in order to be *dissipated* by being neutralized.

In conclusion, I desire to correct a statement about myself made by Mr. Thompson. It was five years ago, not three, that Mr. Thompson, upon my invitation came to a room in the Standard Oil Co.'s new building to witness my experiments with a six plate electrical machine using a spheroid as a cloud. The gas from the gas pipe in the room was used to charge the model oil tank used in the experiments. Profs. Morton, Plympton, and Nason, of Troy, were also present, and the experiments were absolutely successful; but because I refused to dispose of my invention for a trifle, the company refused to adopt it.

I applied the same principle to the U. S. Government magazine, at Dover, N. J.; also to the Wellesly College building at Wellesly, Mass., where 9 conductors, all of which were tested by Prof. Holman, of the Mass. Inst., of Technology, Boston, showed the highest resistance of ground or conductor to be .3 of an ohm. I also predicted the striking of the Washington Monument, giving my reasons for the same, and my prediction was fulfilled when, three weeks later, the capstone was shattered. I was called upon to advise a method of protection, and in response to suggestions, the connection of all masses of metals about the plinth was carried out and a crown with many points substituted for the single aluminum point; since then no further disturbance has occurred.

---

[1] These and the subsequent italics are mine.

ELECTROLYTIC PRODUCTION OF CHLORATE OF POTASH.

THE works at Vallorbes are now producing, the *Bulletin International* says, one ton a day of chlorate of potash by the electrolytic process of Gall-de-Montlaur. The output is one kilogramme (2.2lb.) per horse-power every day of 24 hours. The process consists in electrolysing a solution of 25 per cent. of chloride of potassium at the temperature of 45 deg. to 55 deg. C. Chlorine and potassium are set free, which again react upon the chloride not decomposed, and transform it into chlorate of potash. When the electrolysis is complete, the chlorate is precipitated by successive crystallisations. The manufacture presents several practical difficulties; it is indispensable, among other things, that no metallic particle whatever should come into contact with the baths, on account of the formation of chlorides and oxides, whose presence render the purification difficult, if not impossible. The present works comprise 270 vats, of which half are in actual use. This corresponds to an output of 50,000 litres of solution a day. The anodes are of iron, separated from cathodes of platinum by a porous diaphragm. The temperature of the bath is maintained constant by the passage of the current.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers*

VOL. XI. NEW YORK, JUNE 17, 1891. No. 163.

Every ultimate fact is only the first of a new series. Every general law is only a particular fact of some more general law presently to disclose itself. There is no outside, no enclosing wall, no circumference to us.—Emerson.

SUB-CELLAR ELECTRIC RAPID TRANSIT.

THERE has been remarkably little show of opposition to the plan of underground electric rapid transit as proposed by the Rapid Transit Commission for New York City. Not only has there been a general approval of the plan in New York, but outside, where people are in a position to judge freely and impartially, the commendation has been very hearty. Visitors to New York are more impressed with its lack of travel facilities than are the inhabitants, who long since came to the conclusion that they must necessarily be crowded while in the cars and deafened or becindered when walking near them.

The main criticism or opposition has come from two papers, the *Morning Journal* and the *Sun.* The chief objection of the former seems to lie against the tunnel as a tunnel, and not against electricity as a motive power. And yet there is no evidence to prove that the tunnel now being operated in this way in London is in the slightest degree offensive to health or to any of the senses. The London correspondent of the *New York Times* testifies to the direct contrary. So does the London correspondent of the *Boston Herald,* who says: "What impresses you with decided favor is the *brightness* and *lightness* and *cleanliness* of the whole thing. The electric current gives light as well as motion, *the air is fresh,* the coaches are comfortable and the speed delightful." And such is the testimony of every person we have seen who has taken a ride over the road.

But the *New York Sun,* which in a ponderously humorous way has been trying to make fun of what it calls "sub-cellar rapid transit," wants to know, you know, whether people prefer to travel in the air and sunshine or in a clammy, unwholesome, stuffy atmosphere, with poor lights and every possible discomfort. Well, it happens that it is quite the other way, you know, for if ever people traveled in a clammy, unwholesome, stuffy atmosphere, with poor lights and every possible discomfort, they do it now pretty well every day of their lives on the Elevated Railroads of New York.

But the *Sun* is not satisfied with its false parallel. It goes on as follows at another time, in comment upon some excellent remarks made by the *Philadelphia Press:*

> The Rapid Transit Commission report provides that the motive power of the proposed underground railway "shall be electricity or some other power not requiring combustion within the tunnel." The length of the road is to be twenty miles. No system which will not enable trains of four or five cars to pass over this distance in three quarters of an hour, at the slowest estimation, deserves the name of rapid transit. Longer trains will in all probability be necessary. A speed of at least thirty miles an hour will be indispensable. The accomplished engineers of the Commission may be able to report to it that they have found a motive power equal to the task, but if they have, the discovery will be a surprise to the world. The cable system is out of the question. It is unequal to providing within ten miles an hour of the requisite speed, and, besides, the cables are always breaking. Does the *Philadelphia Press,* or anybody else, know of an electric motor which can draw even one loaded passenger car at the rate of thirty miles an hour, or even of twenty miles an hour? Until such an electric motor or some other motor not dependent upon combustion can be constructed there can be no underground rapid transit answering the conditions prescribed by the Rapid Transit Commission.

All we have to say is that electric motors to-day, all over this country, are doing just such work, and that in the service between St. Paul and Minneapolis they have been so successful that they have already supplanted the old steam service. More than five years ago we had the pleasure ourselves of riding behind electric motors under just such conditions and have done it many a time since. There is nothing at all wonderful or extraordinary about it. The amazing thing is that the *Sun* should allow itself to remain in such utter ignorance of what electricity is doing in the field of locomotion. It is a paper from which one expects, and generally gets, much better things.

Still we are not seeking the unsatisfactory resource of mere rhetorical controversy, nor do we care to ply our readers with facts that they long since became familiar with. We are relieved of the necessity, if it exist, of pushing the matter, by the flat-footed challenge to the *Sun* from Mr. Frank J. Sprague, published in the Saturday *Evening Post.* Mr. Sprague there puts himself under a fine of $50,000 to meet just exactly the conditions that the *Sun* intimates cannot be met, and adds other conditions to make the task as onerous as any that could occur with the proposed underground electric rapid transit system. The opponents of the plan on the ground of its electrical impracticability can either take up the challange or, to put it plainly, "shut up."

REFORM IN TAXATION.

ONE by one "Campaigns of Education" on public questions are undertaken by public-spirited citizens who have the will and courage to put their convictions into expressions and actions. The movement for civil service reform, both

National and State, has gone far and accomplished much; the agitation of the past few years for tariff reform has awakened or created a wide-spead belief that the existing economic system is neither just nor wise. It is further encouraging to note the formation of the New York State Tax Reform Association. Its aims and objects are set forth in a circular as follows:

1. The most direct taxation is theoretically the best, because it gives to the real payers of taxes a conscious and direct pecuniary interest in honest and economical government.
2. Mortgages and capital engaged in production of trade should be exempt from taxation, because taxes on such capital tend to drive it away, to put a premium on dishonesty and to discourage industry.
3. Real estate should bear the main burden of taxation, because such taxes can be most easily, cheaply and certainly collected.
4. Our present system of levying and collecting State and municipal taxes is extremely bad; spasmodic and unreflecting tinkering with it is unlikely to result in substantial improvements.
5. No legislature will venture to enact a good system of local taxation until the people, especially the farmers, perceive the correct principles of taxation and see the folly of taxing personal property.

The principles thus set forth will doubtless secure the assent of many citizens who have given some serious thought to the subject of taxation. Their advocacy and public discussion may fairly be expected to bring about a more adequate comprehension of the general subject on the part of voters, and a more enlightened sense of their true interests as tax-payers. Directness of taxation and certainty in assessment—which latter desideratum can never be achieved as to personal property without an inquisitorial process wholly intolerable to self-respecting citizens—are principles well established in the minds of students and investigators, but they have not yet secured acceptance by the general public, and particularly have not attained the assent of the farmers. If the Tax Reform Association succeed in convincing the holders of farm property that it will be money in their pockets to release mortagages and other personal property from tax, the battle for tax reform will have been won. There are abundant indications that the rural voters throughout the country are keenly aware that much is amiss in National and State taxation. The inauguration of the New York Tax Reform Association is timely and promising. It is gratifying to observe the name of so distinguished an authority and expert in economics as Hon. David A. Wells heading the list of signatures to the preliminary circular of the Association.

The secretary of the Association is Mr. Bolton Hall, and its address is Room 99, 111 Broadway, New York. Mr. Hall invites correspondence and co-operation from all who appreciate the need of more systematic and enlightened methods of raising the revenue of the state.

LIGHTNING CONDUCTORS.

The controversy which was carried some time ago in England between Dr. Lodge on one side and Mr. Preece on the other has done probably more than anything within recent years to call attention to the diversity of opinion which still exists on the subject of the proper protection of buildings from lightning. The theories advanced by Dr. Lodge were in consonance with the results of his experiments on the alternative path, and the side flash of neighboring conductors was also introduced as a prominent factor. Mr. Preece, on the other hand, contended that, without seeking new theories, the results of the best past practice were a sufficient guide for our future course in the protection of buildings and apparatus from lightning. This controversy has hardly died away before we are confronted with a new theory involving a radical change in the construction of lightning conductors, due to Mr. N. D. C. Hodges, who contends that by employing a dissipatible conductor the potential of the lightning discharge can be lowered sufficiently to deprive it of its destructive qualities. We believe that Mr. Hodges has not yet had occasion to demonstrate the correctness of his theory by the erection of a lightning conductor constructed on this plan, and hence the subject is still open for discussion. It is for this reason that we give space this week to a few remarks from Capt. C. J. Hubbell, in which he cites experience in support of his arguments, controverting the theory of Mr. Hodges. It seems indeed strange that the earliest practical application of electrical science, the lightning conductor, should still be a debatable subject; and stranger still that, following the discussion of the relative merits of the rod or the tape form, which began with Faraday and Harris, we should now be discussing solid or dissipatible conductors.

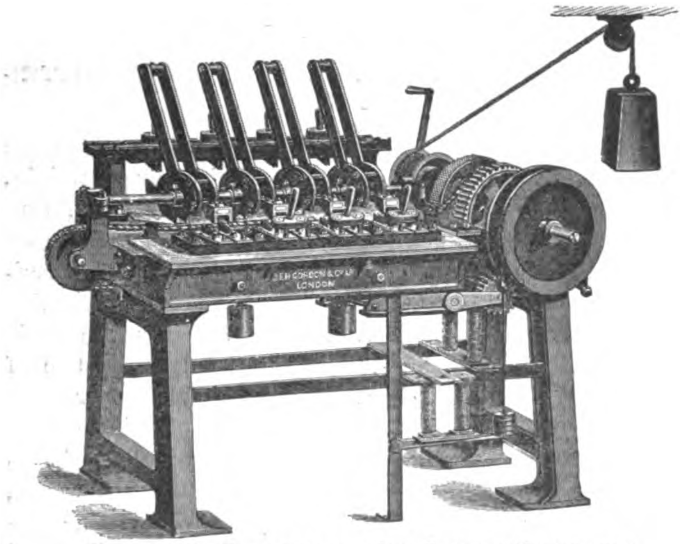
SIR WILLIAM THOMSON ON METHODS OF DISTRIBUTION.

The eminent position occupied by Sir William Thomson gives his utterance on any electrical subject great weight, and, as such, a recent report of his on the electric lighting of Glasgow, together with some comments on analogous subjects, before the London Institution of Electrical Engineers, has, it seems, attracted considerable attention abroad. In the report referred to, Sir William recommends the city to adopt the low-tension direct current system of distribution, which he characterizes to be for many reasons decidedly preferable to the high-tension alternating current with transformers, adding that the supply ought to be as near as may be to the district to be lighted, and the nearer, the better for economy. He also advocated the same system, as above stated, before the Institution of Electrical Engineers on account of the great simplicity which this method possesses. We believe that no one will find fault with Sir William's suggestions if properly analyzed. As he says, the great simplicity of the direct system makes it the one to be employed of all others, where the conditions allow of its use, and such evidently appear to be those obtaining at Glasgow. But we do not think that Sir William intended to convey the impression that the low-tension direct system was the one best adapted to all conditions of supply. It is true that electricians, especially in England, are inclining more and more to house distribution at low pressure from sub-stations, and with good reason; but this is independent of the kind of current employed, and can be said with equal truth of both the direct and the alternating system. No one will deny, probably, that the direct system of supply is simpler in some respects than that of the indirect method with converters, but the great advantages of the latter, where the conditions call for its employment, far outweigh this objection. The alternating current system of distribution needs no defence at our hands, and it is safe to say that the remarkable progress in electric lighting is largely due to this system, with its capacity for economically covering wide areas of distribution from a single point.

THE TOMLINSON SUB-STATION REGULATOR.

As electrical engineers become more fully alive to the waste of power in transformers kept in circuit all day at light loads, the sub-station method of distributing alternating currents is coming to the front more and more. Mr. J. E. H. Gordon, of London, has recently exhibited a most ingenious sub-station regulator, the invention of Mr. Thomas Tomlinson, and designed for cases where there are a number of transformers at each sub-station.

The Tomlinson apparatus, shown in the accompanying illustration, is provided with four sets of switches, and the transformers are arranged in five groups. One group is permanently connected to the mains, and one more is connected through each set of switches respectively. Suppose that one transformer is permanently connected to the mains; then one would be connected to the first switch, two to the second, four to the third, and eight to the fourth, so that the putting in of each switch doubles the number of transformers in circuit. With a current of 1,500 lamps on a single switch no spark whatever is visible. The switches are thrown over by a sliding carriage in the form of a double wedge, which runs backwards and forwards along the bed-plate of the machine, and, as it passes each switch, throws over a tumbling lever, which strikes the switch suddenly in or out of contact.



Tomlinson's Transformer Sub-Station Regulator.

This carriage is moved by an endless chain actuated by two weights, which are released respectively by two electromagnets. The large weight which takes the transformers out of circuit has to be wound up once a week, and, as it takes out the transformers, it at the same time winds up a smaller weight ready to put them in again. If any failure whatever of the large driving weight occurs, or if the attendant forgets to wind it up, the small weight is always ready to put the whole of the transformers into circuit, and must do this before the apparatus becomes inoperative.

The apparatus has been tried practically through the courtesy of the Brush Company, the Electric Construction Company having also lent transformers for the experiment. The plant was first run for twenty-four hours with the transformers connected in the ordinary manner, and then for twenty-four hours connected through the Tomlinson regulator, and coal and water were measured throughout the experiments. The actual saving in coal was carefully determined, and the use of the regulator showed a saving amounting to an extra dividend of nearly two per cent.

Mr. L. W. Dillon, of the Attleboro, Mass., Electric Light Co. has, under the new organization been appointed superintendent of the electric company and the street railway company.

ELECTRIC FORGING.

BY

Otis K. Stuart.

The most valuable feature of electric forging is, perhaps, the power it gives us of *localizing* heat in a mass of metal. The only portion of a metal rod heated in an electric forger is the length between the two clamps, and obviously this may be made longer or shorter at will, it being necessary merely to increase or decrease the electromotive force of the secondary current accordingly. And this is obviously true of all metals, whether of high or low electrical resistance, whether of high or low melting temperature, whether the pieces be of large or small sectional area. It is thus possible to generate the heat just where it is desired to perform the forging operations, and the original shape of other portions is thereby retained—a difficult feat to accomplish oftentimes by the ordinary methods.

The chief reason, perhaps, why electric forging has not been introduced into the metal working industries as yet, is that it is too *expensive*. Electric welding is economical as compared with ordinary forge and hammer welding, because the operations can be performed with greater rapidity and the heat can be confined to the *ends* of the pieces to be joined. The smallest amount of time and a minimum amount of heat are required. But in forging operations large masses must generally be heated, and it is well-known that the production of heat by electricity is an exceedingly expensive process. Besides, the vast mass of forging which is done in the shops of this country is on pieces of metal which vary infinitely in shape and size, and thus clamping would be difficult, as good contact must be secured between the clamps and the pieces to be forged, and it would be impossible to build apparatus which could perform such a great variety of motions as would be necessary to give a variety of shapes to the metal. It has been found impossible to make a universal welding machine, but it would be far more difficult to make a universal electric forging machine, because the latter, from the very necessities of the case, would be a much more complex apparatus.

Still, as we stated above, the great objection to the electric process of forging is the expense of generating the heat. Even if pieces of iron no larger than 2″ diameter and 6″ length are to be heated to a temperature high enough for easy forging, about 75 horse-power would be required for several minutes. If copper is to be worked, still more power would be necessary. Smaller sections require proportionally less power, as the power necessary to heat metal varies, if radiation be left out of the estimation, directly as the masses of the pieces. It is clear that for use in large work, thousands of horsepower would be required, which would necessitate enormous engines or equally gigantic water powers. If the latter can be found and utilized, there would seem to be no reason why we should not then have immense forge shops in which not an ounce of coal would be burned, but all the heat for forging purposes would be generated from the energy of a waterfall through the medium of electricity. And until then, I do not look for any very considerable expansion of the electric forging industry.

FRANKFORT EXHIBITION.

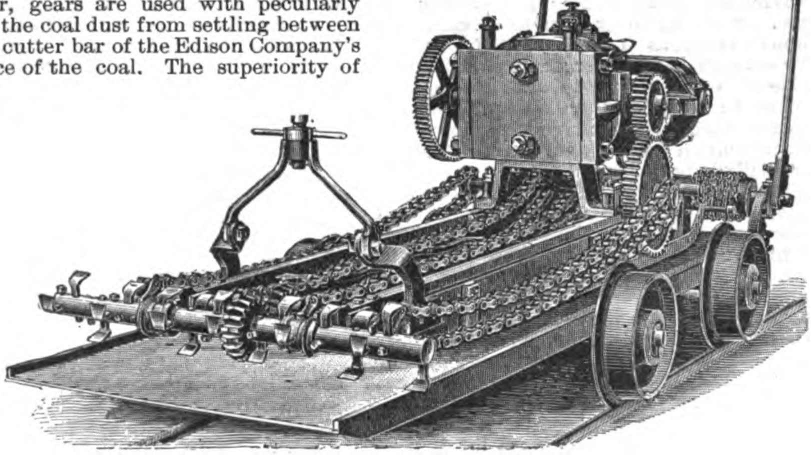
The work for the installation of the 300 h. p. transmission from Lauffen to the exhibition is being rapidly pushed forward. The 10,000 oil insulators required are already supplied, and the turbine at Lauffen is being erected. The work of manufacture of the electrical apparatus by the Allgemeine Company is being pressed forward, and it is expected that the whole will be ready well within the time stipulated.

THE EDISON GENERAL ELECTRIC CO.'S COAL CUTTER.

Of the many different coal cutters in use at present, those that have so far met with the best success are undoubtedly those using the cutter bar, that is, a shaft revolving parallel with the coal in a horizontal plane, and having knives distributed all around the surface, so as to cut a groove in the coal the entire length of the bar. The type of coal cutter adopted by the Edison General Electric Company, and shown in the accompanying illustration, has been in use for years, and has been thoroughly tested. This machine has the advantage of great strength, and is especially excellent as regards the design and the distribution of the material to give the necessary strength and rigidity. A special feature is that the cutter bar revolves in such a direction that the coal is cut upward. This method greatly assists gravity in holding the machine down to the ground, and to a great extent avoids the necessity of carefully fastening it by means of braces or jacks.

With machines using the cutter bar, the bearings holding this bar have necessarily to be very short, for otherwise the ridge of coal left standing in front of them, which cannot be reached by the cutters, would be too wide and strong to be readily broken away by the wedge-shaped front of the bearing. It has been customary to make these bearings 1¼ inches wide, and to transmit the power to the cutter bar direct by means of a chain. In this manner the cutter bar has not only to withstand the strain due to the resistance of the coal being cut, but also that of the chain itself, which, when 15 horse-power is transmitted to the cutter bar, amounts to 3,600 pounds.

The Edison Company has adopted a countershaft behind the cutter bar, to which the power is transmitted direct from the motor by means of four chains. This countershaft has bearings 6 inches long, and strong enough to withstand any strain the chains may exert on them. To transmit the power from the countershaft to the cutter bar, gears are used with peculiarly shaped teeth, which prevent the coal dust from settling between them. The only strain on the cutter bar of the Edison Company's machine is due to the resistance of the coal. The superiority of this construction is evident, when it is considered that the bar is very much weakened by the number of holes drilled in it to receive the cutting tools and the set screws required to hold them. The cutter bar is now about as strong as it can well be made. Any increase in diameter would also increase the height of the cut, which already is 4½ to 5 inches high.



Edison Electric Coal Digger.

There are other advantages in the design of the machine used by the Edison Company which make it adapted to withstand the rough usage to which it is subjected in mines. Among them can be named simplicity in design of the feeding devices, and the use of rollers for the sliding frame, which reduce to a minimum the friction between it and the stationary bed, and decrease the danger of binding between the two.

To determine the amount of power required for coal cutters, a number of tests were recently made with machines at work in coal of varying degrees of hardness. These tests have shown that a 15 horse-power motor is sufficient for the purpose. In some places the power required exceeded this amount, but as the machines only ran off and on, having their full load on for about four minutes at a time, a motor having the capacity mentioned was found to be sufficient; and a careful examination of the condition of the armature and magnet of the machine showed them to be perfectly cool.

The motor used for the Edison General Electric Co.'s coal cutter is capable of giving 15 horse-power when doing steady work. When running off and on only, as would be the case when used with coal cutters, it is capable of giving far greater power. This motor is especially well adapted to the work it has to perform; it runs entirely without sparking, and has all its vital parts well protected.

The Edison Company builds coal cutters capable of making a cut 4 feet, 5 feet, and 6 feet deep, by 3½ feet wide. They are all provided with trucks, by means of which they can readily be moved from place to place. The devices on the truck to load and unload the machines are very simple and efficient, and each machine is supplied with a cable 150 feet in length, and provided with devices to enable it to be readily attached to the main wires.

The average cost of equipping a mine with the electric plant necessary for mining 400 tons per day in a 5-foot vein of soft coal (the plant being operated 20 hours per day), is estimated at $9,500 exclusive of steam engine, boilers, and building.

THE DETROIT ELECTRICAL WORKS.

There is nothing small about the way in which the Detroit Electrical works is organizing its business and shops, with the determination of becoming one of the most prominent factors in the electric railway and motor field. It has just closed a real estate deal which gives it a block of 16 acres in Detroit, between Twelfth street and Wabash avenue, with a frontage of 453 feet on the Grand Trunk railroad. The Detroit Electrical Works contemplate putting up there one of the most extensive electrical manufacturing establishments in the country. The new works will include a machine shop, foundries, pattern shops, finishing shops, steam forges, erecting shops, carpenter shops and laboratories, and possibly a large power plant capable of furnishing electric current for the motors of the whole manufacturing establishment. The present works will be continued in operation for the manufacture of various kinds of electrical supplies and machinery.

The mechanical shop of the new works will be a large structure and each department of the work will be entirely separated from the others. All of the shops will be fitted up with overhead electrical traveling cranes, and they will be used for the manufacture of electrical machinery in its various forms, as may be developed from time to time. The intention for the next year's work is to turn out at least five complete steel car electrical equipments per day and one complete generator of a capacity of not less than 100 h. p.

The cost of the buildings as now contemplated will be from $200,000 to $300,000, including the amount of machinery that will be necessary over and above what can be transferred from the old works at the Woodward avenue railroad crossing. The plans and specifications are not yet complete, but they are expected to be finished so that work may be commenced in July and the works ready for operation by Jan. 1. The purchase of the property was completed only last week, and no time will be lost in erecting the new structures.

Extending down the middle of the property will be two railroad tracks connected at suitable points by cross-over switches. An overhead trolley system will be erected throughout the grounds, and electrical locomotives will be used for all shifting work. All buildings will be of fire-proof construction, and while not elaborate in design will be as little objectionable from an architectural standpoint in exterior appearances as strength and neatness will permit.

The present works are now running three hours overtime, besides employing the entire facilities of the Dry-Dock Engine Works in turning out the different mechanical parts of new equipment.

Louis Warfield, lately of the Pennsylvania Railroad Co., is now general manager and treasurer of the company. The other officers are: President, Hugh McMillan; vice-president, William A. Jackson; secretary, William H. Wells.

Society and Club Notes.

NATIONAL ELECTRIC LIGHT ASSOCIATION.

The Executive committee of the Association was exceedingly well received during its recent meeting in Montreal, and the interest shown in their proceedings is an excellent augury for the convention September 7, 8 and 9, as proposed. A strong local committee has been formed and is now at work. During their visit the N. E. L. A. representatives were most hospitably entertained. They were first welcomed by Mayor M. C. Shane and Alderman Stevenson, in behalf of the city, and ex-Mayor Beaugrand, in behalf of the French-Canadian population. Prof. Bovey stated that in all probability Lord Stanley would attend the meeting in September. In the afternoon the visitors, under guidance of Prof. Bovey, inspected the technical and electrical departments of McGill University. They were then taken to ex-Mayor Beaugrand's house, for refreshments; thence to call on Mayor McShane at the City Hall, and thence to the Mountain Summit. In the evening they were given a dinner at the Windsor Hotel by the Citizens' Committee, with Prof. Bovey in the chair. Among the speakers were Messrs. J. Kennedy, President Huntley, Beaugrand, Cox, Fairbanks, E. F. Peck, Corriveau, Villeneuve and Stevenson.

THE FRANKLIN EXPERIMENTAL CLUB.

At the thirty-third regular meeting of the Franklin Experimental Club, held at the club laboratory in Newark, N. J., on the 2nd inst., two papers were read. One was presented by Mr. Wm. J. Hammer and was entitled "Some Facts and Phenomena about Incandescent Lamps."

In the course of his paper Mr. Hammer showed that filaments of carbon are preferable to metals, as carbon is far more refractory and is of higher resistance. A vegetable or structural carbon is preferable to a homogenous carbon, as it is, first, mechanically stronger, just as a hollow column is stronger than a solid one; then the walls of vegetable cells are very thin and give a high resistance with a shorter length of carbon than is possible with a homogenous one. This is the reason why nearly all homogeneous carbon filaments are either curled or twisted, or, if straight, compel the use of exceptionally long globes.

Carbons after being placed in the globes are always "tempered" or "flashed," commencing with a small current and finally running up to several times the candle power at which the lamps will be run normally. This weeds out the poor filaments, and drives out the occluded gases in the carbon, clamp, and platinum wires in the lamps.

The vacuum in an incandescent lamp varies from one one-hundred thousandth to one-half millionth of an atmosphere. Generally it is even less than the former. Formerly it was supposed that too high a vacuum could not be attained, but it is now known that there is less strain and disintegration of the carbon and less blackening of the glass at lower vacuums.

At times one sees a lamp which burns much more dimly than others upon the same circuit and of the same rated candle power. This is probably due to a crack in the glass globe and the gradual admission of oxygen which is causing the carbon to be consumed. An evidence of this will be found in the exceedingly hot globe; also in the spotting of the carbon, which will become bright in spots and gradually waste away until it suddenly breaks at one of the bright spots. An incandescent lamp will last longer in a thin globe than in a thick one, as the heat rays pass through the thin glass and escape, while the thick one holds them and so lessens the life of the lamp. Incandescent lamps are longer lived on continuous than on alternating currents, the rapid reversals of the current shortening the life of the filaments. About 45 per cent. of the lamps in central stations are replaced before breaking, owing to blackening of the globes or to the carbons becoming too thin, thus giving less light.

Mr. Hammer believed that carbons would eventually be placed inside of dishes, cups, etc., electrically connected so as to keep their contents warmed.

The second paper was presented by Mr. Earl Atkinson, entitled, "Electric Motors." Mr. Atkinson first took up the subject in a general way, describing the more recent achievements and the present state of the art. He said that while the tendency was toward larger motors in some cases, in others it was toward a large number of small motors, as, for instance, in certain lines of manufactures where each machine was provided with its own separate motor. He then took up the questions more particularly involved in the design and construction of street car motors. These involve the questions of ability to endure, without injury, the great and sudden changes of load at starting, as well as to be run in either direction. Mr. Atkinson stated it as his opinion that when it becomes possible to provide street cars with satisfactory storage batteries connected to slow speed motors attached directly to the car axle, the resulting service will be all that can be desired.

NEW YORK ELECTRIC CLUB.

A smoking concert will given at the Club Thursday evening, June 18th, at eight o'clock. This is the first entertainment of the kind attempted by the Club, and it is believed that, the occasion will be a very enjoyable one. Members will contribute to the programme, which will include several original and novel productions. A business meeting of the Club will be held after the smoking concert.

Literature.

NEW BOOKS.

A Popular Lecture on Light. By Prof. Elihu Thomson, Lynn, Mass., *John W. Gibboney.* Pamphlet. Paper Cover. Price 20 cents.

Those who have had the pleasure of listening to Prof. Elihu Thomson in his exposé of scientific principles and their practical applications relating to matters electrical, will find in this little pamphlet the application of a method of treatment which has made him probably the model scientific lecturer of this country. While turning aside in this instance, somewhat from the work which lies nearest to his hand, Prof. Thomson is evidently at no disadvantage, and shows up especially the intimate relation which exists between electric phenomena and those of light, the lecture table having been equipped with a variety of electrical apparatus to demonstrate his remarks. Prof. Thomson begins by showing that we have ample proof that light is due to electrical vibrations of ether, and then passes in review the mode of propagation of light and its composition with regard to color. Then come the various methods of obtaining artificial light, passing from the primitive tallow dip to the most modern methods of electric illumination practiced to-day. Prof. Thomson also shows that if we could produce an alternating machine with a sufficiently large frequency of reversal, lamps would not be needed, as the whole machine itself and the wires proceeding from it would glow with light. He points out, however, the mechanical difficulties standing in the way of the production of a machine capable of giving such a large number of alternations. In conclusion, the lecturer dwells upon the cold light met with in the fire-fly and the Geissler tube. We can recommend the lecture as one which will absorb the attention of the reader throughout.

Arithmetic of Electricity. By T. O'Connor Sloane, Ph. D. New York, 1891. *Norman W. Henley & Co.* 138 pages, 5 x 7 inches. Price, $1.

THERE are many problems which occur in the construction of electrical apparatus, electric lighting and distribution of power which can be solved arithmetically, and a work which will enable those not fully equipped mathematically to perform these operations, therefore, has a distinct place in electrical literature. Our readers will recall a work of this character by R. E. Day, which appeared some ten years ago, and which deservedly met with general recognition. The work before us is based on the same lines, but the author has added much that will be found of value to those to whom algebraical formula are unintelligible. The plan upon which the book is based is to give first the rule in simple language, and then to follow it by an example showing the method of its application. In this way the author passes through the various applications of Ohm's law, the calculation of the resistance of conductors, potential differences, the area of wires to carry various currents, both for the two and three wire system, and the calculation of electrical work and energy, batteries, etc. To these are added a number of excellent rules on the construction of electro-magnets, dynamos and motors, in which are introduced the latest information on the subject, and referred to the C. G. S. system. Following the rules and examples the author has very wisely added a chapter in which he demonstrates the rules and gives the formula, together with the data, from which the rules are derived. The length of some of the rules given in the earlier part of the work would appear to have made it worth while to have introduced the formula at that time, simultaneously with the rule, in order to make its application clear. Thus, on page 44, we find a rule extending over six lines which it would be very difficult to apply in practice without the formula. To the contents just noted there has been added a series of tables with equivalents of units of work and energy, electrical resistance, thermo-electric equivalents, and various magnetic and electrical data.

While the book is not entirely free from errors, we believe that their nature is such as not to detract seriously from its undoubted value; but we hope that future editions may be more carefully proof-read. We can recommend the work to those seeking methods of direct application of principles to many problems met with in the electrical engineering of to-day.

MR. SPRAGUE'S CHALLENGE TO THE "NEW YORK SUN."

In the *Evening Post* of June 13 Mr. Frank J. Sprague, meeting the incredulity, affected or real, of the *New York Sun* as to the ability of an electric motor to haul a single elevated railroad car full of passengers at 30 miles an hour, made the following challenge:

> Let a section two miles long be provided on the Second Avenue, the Suburban or the New York and Northern Railway, which shall fairly represent a station section of the express track on the proposed underground road for use at night when not required for regular traffic.
>
> Set apart a train of six standard elevated cars. These will weigh when empty 71 tons, and can carry when crowded to the utmost about 500 passengers, weighing 37 tons, making a net weight of train without motive power of 108 tons.
>
> Let this loaded six-car train be propelled in two ways:
>
> (1.) By a separate electric locomotive.
>
> (2.) By a system of motors, one on each truck, all controlled from a pilot locomotive.
>
> Let the condition of operation be:
>
> (1.) A maximum speed of not less than 40 miles per hour on a level.
>
> (2.) Power to stop the train without the use of brake shoes and independently of the main station current.
>
> These requirements, both as to weight and speed, are double those now characterizing the operation of the London road, and represent a capacity of eight times that mentioned in the criticism.
>
> I will undertake to make this demonstration prior to the formation of a construction company, with free subsequent competition for regular equipment under either of these conditions:
>
> (1.) The Rapid Transit Commission to require the successful bidder for the franchise to pay the costs of the experiment to an amount not exceeding $50,000.
>
> (2.) The forfeiture of a like sum, in case I succeed within a specified time, by any person or newspaper that will take up my challenge.
>
> (3.) On the other hand, entire loss to me if I fail.
>
> (4.) The time to be four months from acceptance of this proposal, barring labor troubles, with one month leeway, at a forfeiture to me of $100 a day for each day of the month over the four months, and a premium of like amount for every day under four months. If the cost of the experiment shall be less than $50,000, the saving to go to the benefit of whoever pays for the demonstration.
>
> It will be noticed that this experiment is entirely at my personal risk, with time limitation, and without any direct pecuniary value to me, but is proposed to demonstrate the soundness of the decision made.
>
> As an evidence of my good faith, I am ready to deposit a sum which will guarantee the good faith of this proposal.

Reports of Companies.

THOMSON EUROPEAN ELECTRIC WELDING CO.

At the annual meeting of the Thomson European Electric Welding Company, at Portland Me., the following named directors were chosen: Oliver Ames, Benjamin F. Spinney, George P. Meserve, S. Endicott Peabody, Henry D. Hyde, Prentiss Cummings, Joseph N. Swett, Royal G. Robbins and Francis Peabody, jr.

WESTERN UNION TELEGRAPH CO.

The Directors of the Western Union have declared the regular quarterly dividend of 1¼ per cent. payable July 15. The statement for the quarter shows a decrease in net revenue of $250,000. For the fiscal year ending June 30 the net revenue over charges decreased $780,285 from the previous year, but was $162,324 in excess of the year to June 30, 1889. The surplus over dividends for the year was $1,274,996 against $1,408,978 to June 30, 1890, and $1,112,853 in 1889. It was officially stated that the company has 4,642 stockholders, the largest number in its history.

TROPICAL AMERICAN TELEPHONE CO.

The Tropical American Telephone Co., Limited, presents the following statement of assets and liabilities, as of date Jan. 1, 1891 · Assets—Bills receivable, $30,999.36; merchandise on hand, $11,400; treasury stock, 3,000 shares, $3,000; cash in bank, $8,232.14; total, $53.631.50. Liabilities—Bills payable, $2,505.39; balance, $51,126.11, or $1.25 per share. This balance is aside from patents, franchises and contracts. The capital of the company is $400,000, 37,000 shares issued, par value $10 each. The company's sales last year were rising $100,000, and the sales for the six months to Jan. 1, rising to $56,000. At the Jamaica Exposition the company was awarded a gold medal for its tropical telephone sets, both for long distance and for commercial uses.

ERIE TELEGRAPH AND TELEPHONE CO.

The annual meeting of the stockholders of the Erie Telegraph and Telephone Company was held last week in this city. The following officers were elected: Levi Sprague, president; Charles J. Glidden, secretary and treasurer; James P. McKinstry, general manager; and the following executive committee of the board; Abner S. Adams, Charles E. Adams, Charles J. Glidden, Wesley A. Gove, Francis Jewett, James W. C. Pickering, Asa C. Russell, Levi Sprague, James A Weston, and Harvey A. Whiting.

College Notes.

SCHOOL OF MINES, COLUMBIA COLLEGE.

The first class in electrical engineering graduated from Columbia College at commencement, June 10. The men to receive the new degree of electrical engineer (E. E.) are Gano S. Dunn, B. S.; Wm. H. Freedman, C. E.; Arthur S. Ives, C. E.; Joseph T. Monell, C. E., and Robert B. Owens. These men are post-graduate students, having all received a thorough collegiate education before taking the two years' course entirely devoted to electricel engineering work. This plan of first getting a thorough preparatory education and then concentrating the mind thus trained upon electrical work exclusively is found to give the most excellent results.

ELECTRIC HEADLIGHTS.

One of the lamps of the National Electric Headlight Co. is now in use, says the *Railroad Gazette*, on the Wilmington & Northern, where it has been running for several weeks. The use of this headlight is increasing in the West, and engines are now equiped with it on the Indianapolis, Decatur & Western; Vandalia; Cincinnati, Hamilton & Dayton; Columbus, Hocking Malley & Toledo; Louisville, New Albany & Chicago; Chicago & Eastern Illinois; Milwaukee, Lake Shore & Western, and the Wabash roads. Officers express great satisfaction with it, and the makers say that no engineer who has ever run behind one of these lights for any length of time, short or long, has failed to become enthusiastic in its praise.

ELECTRICAL EXECUTION.

The New York State Court of Appeals has denied the motion for a reargument in the case of the Japanese murderer, condemned to die by electrical execution, and has sharply criticised the resort to means of delay subverting the criminal law of the State.

SARGENT & LUNDY.

McIntosh, Seymour & Co., through their Western agents, Sargent & Lundy, 339 "The Rookery," have received orders for two 500 h. p. engines from the Chicago Edison Co,, to be used in increasing the capacity of their Adam street station. This makes nine of these engines, aggregating 2,650 h. p. now in use, which the Chicago Edison Co. have purchased for their central station work in this city from this firm. Sargent & Lundy have also received orders for a 150 h. p. compound engine for The Hyde Park Illuminating Co.'s new central station at Grand Crossing. It is very gratifying to note that so many of these high class engines are being installed in the West, where the excellence of their construction and service is highly appreciated.

QUOTATIONS ON ELECTRICAL STOCKS.

F. Z. Maguire & Co., Electrical Securities, of 18 Wall street, this city, report the following quotations of June 13, 1891, from New York, Boston and Washington:

Letters to the Editor.

Notice to Correspondents.

We do not hold ourselves responsible for the opinions of our correspondents.
Anonymous communications cannot be noticed.
The Editor respectfully requests that all communications may be drawn up as briefly and as much to the point as possible.
In order to facilitate reference, correspondents, when referring to any letter previously inserted, will oblige by mentioning the page on which it appears.
Sketches and drawings for illustrations should be on separate pieces of paper.
All communications should be addressed EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

SOME OBSERVATIONS ON THE EDISON LAMP PATENT.

AFTER nearly eight days of solid argument by an array of half a dozen of the most learned and able patent lawyers in the land, the great case of the Edison Electric Light Company against the United States Electric Lighting Company, involving the question of the validity and scope of Edison's principal patent for his incandescent electric lamp, has been submitted to Justice Wallace of the United States Circuit Court for decision. This patent has already passed through the ordeal of litigation in England and in Germany, but the present action is the first in this country in which it has come up for consideration on its merits, though some of the questions involved were to a certain extent passed upon in the suit of the Consolidated Company against the McKeesport Company on the Sawyer-Man patent, which came before Justice Bradley, at Pittsburgh, two years ago.

The aspects in which the present case presents itself are in some respects so peculiar, and they involve moreover so many abstruse questions, not only of equity, but of patent law and patent practice, that the ablest and most experienced lawyers and experts confess themselves exceedingly unwilling to hazard an opinion as to the ultimate outcome of the proceedings. That the industry of modern incandescent lighting is due to the genius and enterprise of Thomas A. Edison, aided by the moral and financial support which he received from the outset through the efforts of Grosvenor P. Lowrey, the eminent counsellor who has just advocated his cause before the court with such consummate ability, is no longer seriously questioned, even by his most determined opponents. That it is the intent of our patent law that the substantial rewards of invention should be of right conferred upon the person or persons to whom the public is justly indebted for the benefits it has received by reason of such invention, is a truism. If in the case at issue there were no other questions than these to be taken into consideration, the ultimate result could scarcely be open to doubt. But the statutes also require the inventor who seeks the protection of a patent to comply with certain well understood conditions, expressed and implied, and in the present case, as in many other important cases which have been heretofore submitted to the courts, it is just at this point that the difficulties arise. If a man buy a piece of real estate, and by reason of his ignorance or of the incompetence of his attorney, his title-deed is found to contain the description of some other property than the one he has bought; or if he fails to have his conveyance placed upon the public records, and is consequently forestalled by some subsequent purchaser who has exercised due diligence in that particular, the law is powerless to aid him. So in case of a patent; the statute requires that an invention shall be described "in such full, clear, concise and exact terms" that the public may be fully instructed how to practice the invention when the patent has expired; and furthermore, that the patentee "shall point out and distinctly claim the part, improvement or combination, which he claims as his invention or discovery," so that as long as the patent is in force, the public may be informed of the precise extent of the claim of the patentee, and may not innocently or ignorantly infringe his exclusive right.

The patent of Alexander Graham Bell for the speaking telephone affords a striking example of the impregnability of a patent, as a protection for an invention not only demonstrably novel, but of vast and unquestioned utility, the specification of which describes and claims in apt language the precise invention of the patentee—no more, no less. The entire description of the speaking telephone in Bell's specification does not exceed 150 words, while the claim is as brief as a claim well can be; but perhaps no patent ever granted in this or any other country has passed unscathed through such a fiery ordeal of litigation. The true explanation of the seeming good fortune which has attended this patent may be given almost in a word; its description and claim are precisely coextensive with the actual invention.

The conception of electric lighting by means of the incandescence of carbon conductors enclosed in a transparent vacuum chamber is nearly half a century old. In the New York *Evening Post*, of October 17, 1844, is an account of the Starr lamp, embodying all the features mentioned above, which afterwards made such a stir when patented in England, by King. The same idea in substance was in subsequent years revived in various forms by different inventors, yet in every instance it failed to attain the slightest commercial success. But the exhibition made by Edison at Menlo Park, in December, 1879, conclusively demonstrated to the world that an invention had finally been made, which, to use a hackneyed but expressive phrase, had "solved the problem of electric lighting by incandescence." What then, it becomes necessary to inquire, was the nature of that invention?

The claims of the patent of Mr. Edison, now the subject of litigation, set forth this invention as follows:—

> 1. An electric lamp for giving light by incandescence, consisting of a filament of carbon of high resistance, made as described, and secured to metallic wires as set forth.
>
> 2. The combination of carbon filaments with a receiver made entirely of glass and conductors passing through the glass, and from which receiver the air is exhausted, for the purpose set forth.

The expert witnesses who have testified in behalf of the Edison company, in the pending case appear to have substantially agreed in their definition of Edison's invention, as consisting of a filament of carbon, of high resistance and small radiating surface, sealed into an exhausted all-glass globe. Justice Bradley, in his opinion in the Sawyer-Man case expressed similar views. He says:—

> "It seems to us . . . . that the great discovery in the art was that of adopting high resistance in the conductor, with a small illuminating surface, and a corresponding diminution in the strength of the current. This was accomplished by Edison in his filamental thread-like conductors, rendered practicable by the perfection of the vacuum in the globe of the lamp. . . . In such a vacuum, the slender filaments of carbon, attenuated to the last degree of fineness, may be maintained in a state of incandescence, without deterioration, for an indefinite time, and with a small degree of electric force. *This was really the grand discovery in the art of electric lighting* without which it could not have become a practical art for the purposes of general use in houses and cities.

The general tenor of the arguments of the distinguished counsel who have represented the Edison interests in the pending case, have been based on a theory of the question at issue substantially the same as that held by Justice Bradley, namely:—"that the art of commercial electric lighting is founded upon the discovery and invention of Edison, and that this consisted in the employment of a filament of carbon of high resistance and small radiating surface, enclosed in a high vacuum. Undoubtedly the language in which the invention is attempted to be described and claimed, in the patent upon which the action has been brought, left the learned gentlemen no alternative but to take this position, and to the best of their ability to urge its acceptance upon the court, but it is nevertheless in point of fact, a question of no small moment, whether the claims of the patent are not based upon a complete, and possibly fatal misconception of the real character of the invention which it was intended to protect. Two circumstances which occurred during the trial at least tend strongly to support such a conclusion. One was the production, by the defendant, of a certified copy of an application from the files of the Patent Office, from which it appeared that Edison had attempted to procure a subsequent patent, defining the invention more accurately, and claiming it more broadly; urging at the same time that the claim of the existing patent (the one now in issue) was limited, and was wholly insufficient adequately to protect his rights. The other was the unavailing effort of the counsel for the defence to obtain, either from the witnesses or the counsel for the complainant, a definitive statement of the precise meaning of the terms "filament" and "high resistance," which form an essential part of Edison's claims. The question was met by dexterous and studiously evasive replies which in fact wholly failed to answer it. It was asked for example, whether a burner of four ohms resistance would be a "filament," and whether such a burner would be of "high resistance" or not, but not the slightest information on that point could be elicited. Now it is perfectly obvious that a burner of four ohms, or of half an ohm for that matter, might embody Edison's real invention, just as completely as one of a thousand ohms, and hence it would seem that the impossibility of satisfactorily answering the question could have been due only to the fact that the claim was not co-extensive with the actual invention, but covered nothing more than some of its incidental and non-essential features. If Edison's claim does not in truth define his invention in such a manner as to enable any person to determine with certainty whether he may or may not make an incandescent lamp with a burner of four ohms resistance or less, without being held liable as an infringer, then it must be null and void, for it clearly contravenes the express provision and purpose of the statute.

A careful consideration of the whole subject can scarcely fail to lead the thoughtful inquirer to the ultimate conclusion that the real invention which raised the incandescent electric lamp from a failure to a success, is to be looked for in the use of *a burner made of carbonizable material of cellular structure, which is first formed and then carbonized*. The real nature of the invention was therefore, to a certain extent recognized and expressed in the claims of the Sawyer-Man patent; but by the language employed in it was limited, first, to "fibrous," which is only one form of cellular carbon, and would therefore exclude, for example, a structureless material like Weston's tamidine, and second, to an "arch or loop for m," which, though usually preferable, is by no means an essential configuration for an electric burner. The modern lamp-carbon is a two-fold invention, a process and a product; just as the telephone is a two-fold invention, a method and an apparatus. Edison's merit therefore, did not consist merely in the engineering expedient of giving to a burner of known material, the capacity of high resistance and small radiating surface but in the adoption of a process and material essentially new, which enabled him to make his burners of any resistance, of any radiating surface, or of any ratio between the one and the other, and of such shape as to meet any possible requirement. To say that this most important invention consisted in nothing more than uniting high resistance with small radiating surface in a conductor, is to belittle it, and is no less absurd that it would be to assert that the invention of the electric telegraph consisted solely in winding the electro-magnet with a conductor of high resistance and many convolutions, because Morse's first apparatus, though fully capable of transmitting intelligence (just as the old electric incandescent lamps were of emitting light), was utterly useless as a practical or commercial instrument, because it would only work through a few feet of wire. The real invention in the case of the telegraph obviously lay in the application of the electro-magnet to the production of arbitrary symbols; the commercial success which came from the adoption of electro-magnets, properly adapted for use on a long line, was a mere matter of electrical engineering; were it otherwise, Henry or Gale, and not Morse, might claim to be regarded as the rightful inventor of the telegraph.

It may perhaps be fairly presumed that the underlying consideration which more than any other influenced the general result arrived at by Justice Bradley in the Sawyer-Man case, was that it is to the labors of Edison, rather than to those of Sawyer & Man that the world is indebted for the boon of incandescent lighting; and it is probable, that on the ground of abstract justice, few will be inclined to dissent from this conclusion. But even admitting this, it is by no means an unprecedented circumstance in legal annals, that a decision, right in itself, may have been reached by a chain of reasoning which fails to withstand critical examination.

With all deference to the views of so eminent a jurist as Justice Bradley, it would certainly seem as if in the case referred to, he might, with better reason, have put the dismissal of the bill of the complainant on the ground that the invention in issue, even if first conceived and experimentally used by Sawyer & Man, has become abandoned and lost to them through the superior diligence of their rival. The world might possibly have ultimately realized the benefits of incandescent lighting through the labors of Sawyer & Man, if no such person as Edison had ever existed, but the fact cannot be gainsaid, that Edison discovered, and so far as the record shows, independently and originally discoved, that the only way to make a successful incandescent lamp-burner, is to carbonize cellular material, and by previously shaping it, to confer upon it that amount of resistance and of radiating surface that might be requisite in any particular case; nor can it be gainsaid that all the incandescent lamps in use at the present moment are a direct result of that discovery or invention.

The courts have uniformly held that the claims of a patent ought to be construed with the utmost liberality permitted by the statute, in order to embrace and protect the invention actually made by a meritorious patentee. But at the same time the court cannot overlook the fact that the office of the claim, as prescribed by the statute, is to point out the precise boundaries and extent of the discovery which the patentee intends to claim as his exclusive property. As Justice Blatchford once observed, "If the claim is so ambiguous and uncertain that its true meaning cannot be made out without resorting to conjecture, or if it includes what is old, then the patent is void." It is just here that the difficulty is likely to arise in the case of the Edison patent. What, for example, are the qualities necessary to constitute a "filament"? Is it a matter of dimensions, or of proportions, or of form, or of structure? Neither the patent, the counsel, nor the scientific witnesses have found themselves able to formulate a definition. What is "high resistance"? Is it high specific resistance, or high total resistance? And by what standard is the height of resistance to be measured? These and many other questions which might be asked are by no means easy to answer, but evidently no such difficulty could have arisen, had the claims of the patent been so worded in the first place as to embrace the real invention which it was sought to protect.

The judgment of the court in this most important case will be awaited with great interest, not only on account of the character of the invention itself, but because of the vast commercial and pecuniary interests which are involved. Whether the patent of Edison will be sustained, and the defendants held to be infringers, thereby giving to the Edison Company, for years to come, the virtual control of the incandescent lamp industry, or whether it will share the fate of the Siemens and Gramme dynamo patents, the Brush single arc lamp patent, and the Gaulard & Gibbs alternate current patent, is a question fraught with important consequences to the future of the few prominent companies in whose hands the electric lighting industries of the country are now mainly concentrated.

BYSTANDER.

NEW YORK CITY,
June 12, 1891.

Legal Notes.

EDISON INCANDESCENT LAMP LITIGATION.—II.

ARGUMENT OF GEN. S. A. DUNCAN.

Upon the opening of Court on May, 28th, Gen. S. A. Duncan commenced his opening argument for the defendant. He said that he apprehended it might at the outset be well to get a clear conception of the problem which Mr. Edison undertook to solve in connection with electric lighting. Was that problem the mere invention of a lamp, or was it one of a broader and more complex nature, calling for invention not in one direction, but in a hundred? The bill of complaint had stated that Mr. Edison addressed himself to the work of inventing a complete system of electric lighting, capable of competing with other forms of illumination, adaptable to general use. It declared that this work necessitated the perfection of many distinct apparatuses; generators, conductors, instruments for regulating the quantity and pressure of the current, meters, lamps, sockets and holders, with many other accessory devices, the whole having been perfected only after many experiments, and frequently embodying distinct inventions. Mr. Edison was early in the field, after the great impulse in the domain of applied electricity which arose from the perfection of the dynamo machine; he had been backed by a powerful syndicate furnishing him with abundance of money, and the results of his labors in the solution of this complex problem are found in the large number of patents subsequently issued to him. In November, 1882, for instance, a circular issued by the Edison company gave a list of no less than 150 patents relating to this system, and many others followed in subsequent years. As early as 1883 the Edison Company were attaching to the packages in which their lamps were sent out, labels professing to indicate the lamp patents under which the company was licensed, 121 in number. Mr. Edison's own account of what he undertook to do, is as follows: "The problem then that I undertook to solve, was, stated generally, the production of the multifarious apparatus, methods and devices, each adapted for use with every other, and all forming a comprehensive system whereby electricity, properly controlled and directed, could de distributed over large areas, through the streets of a city, and supplied to houses in which it would feed incandescent electric lamps of moderate candle-power, which would be entirely under the control of the householder, the whole to be on the same scale as the present system of gas distribution, and affording the same character of convenience to the users."

But other inventors were at work upon this problem contemporaneously with Mr. Edison, and were as early in the field as he. Among them were gentlemen associated with the United States Electric Lighting Company, the defendant in this suit, which had a commercial plant in operation in New York as early as November, 1880, the first central station plant in this country. General Duncan thought he was correct in saying that according to the records no lamps were sold by the Edision Company in 1880, nor until after the organization of that plant by the defendant corporation.

Mr. Lowrey here stated that the manufacture of lamps was not carried on at that time by the Edison company, but by the Edison Lamp Company.

General Duncan, resuming, said that manufacture was begun by the United States Company that year, and that it had sold not less than 36,437 lamps to March 31, 1882, while the Edison Company to January 1, 1882, had sold but 34,597; this shows that those concerns, not to speak of others, were simultaneously at work upon this problem. The Edison Company had behind them as inventor Mr. Edison; the other company had other inventors; each had accumulated a large number of patents. Mr. Hebard says his company owned 131 patents in 1885. Yet the proposition of the Edison Company is, that a single one of the hundreds of patents it owns controls the situation, and through that one patent they propose to throttle this magnificent industry; the tens of millions of dollars invested by other companies is to be destroyed absolutely at the dictation of this company, under this one patent, which is only one of the elements in the general system. From that great mass of hundreds of patents, they single out this one, and say that it is that which solves the whole problem of the subdivision of the electric light. As to the interpretation of that patent, General Duncan said, he would take issue with his friends on the other side. His position was that it produced substantially no impression upon the art; he was willing to credit Mr. Edison whatever was his due by reason of the industry he had displayed, the persistence with which he had pursued the solution of the problem he had set before himself, and the large number of inventions he had made. But they were not now trying the value of any of the other inventions, but whether this one invention was the foundation of all Mr. Edison had done. In passing, he would remark that this was not the only suit pending in this court by this plaintiff agains this defendant; there were 29 other suits, involving a dozen other of the multitudinous patents of the Edison Company, and two or three of these were also styled fundamental patents. Probably if this suit should fail, the Edison Company would appear at final hearing at no distant date, declaring that the inventions patented in the patents there involved were the inventions that solved the problem of electric lighting; that was their position as declared in a New Jersey suit in which a patent for the distribution of current was involved, and in which a very intelligent expert called by the Edison Company, when asked whether the invention here in issue did not play an important part in the solution of the problem of subdivision had said: "Why, the lamp had something to do with the solution of the problem, but lamps enough were known to the world before the invention of Mr. Edison's carbon filament, which would have been good practical commercial lamps if only Mr. Edison's system of distribution had been known in the world, and when Mr. Edison invented that, he solved the problem of electric lighting."

Before examining the prior state of the art, Gen. Duncan said he desired to call the attention of the Court to one expression found in the patent as follows: "In general the attempts of previous persons have been to reduce the resistance of the carbon rod." This can mean but one thing; that previous experimentors or manufacturers of lamps undertook to reduce the specific resistance of the carbon burner, not the total resistance. It seemed to him important that that distinction should be kept sharply in mind throughout the whole discussion. After explaining the difference between specific and total resistance, Gen. Duncan said that most of the work in electric lighting prior to Edison's day had been in arc lighting, and the manufacturers of the pencils sought to make the specific resistance as low as possible in order not to waste energy in passing the current through the pencil. Such pencils were made by well-known processes for various purposes. They were made large and small, and were for sale in Paris and elsewhere; some as small as a millimetre in diameter. Undoubtedly King and Lodyguine, and later Sawyer and Man in their first experiments, purchased for their work on the incandescent lamp such carbons of low specific resistance. That was what this statement in the patent meant; it could not have been true in any other sense, for it was not true that any who were at work in incandescent lighting sought to reduce the total resistance of the burner to the lowest point. Such an interpretation would do violence to well-known laws of electricity familiar to all, and would be at variance with the plain teaching of all the patents illustrating the prior state of the art. If any man had undertaken to make electric lamps on the theory of reducing the total resistance of the burner to a minimum, he would quickly have found himself mistaken, however ignorant he might have been of the laws of electricity. That brought him to make a proposition, which he would suggest as a valuable one to carry through the discussion, and to explain many things which might otherwise seem confusing. High total resistance is, and has always been known as desirable for the burner of an incandescent lamp, whether to be used alone, in series, or in multiple arc. There was no mystery about it; the whole principle underlying the incandescent lamp is that of a continuous circuit traversed by the current. If one part of the circuit is of higher resistance than the rest, more heat is developed at that point; the higher the relative resistance, the more heat is developed, and the more light is obtained. It is wholly immaterial whether the circuit contains one lamp or fifty lamps in series, or fifty lamps in multiple arc. The term high resistance used in this art is a merely ralative term; it is high total resistance; the resistance of that part of the circuit in which useful work is done, as compared with the resistance of all the other parts. The essential thing in making an incandescent lamp is to interpose in the circuit at the point where the light is wanted, a resistance body whose total resistance shall be high relative to that of the other parts of the circuit, and the higher that ratio the more economical will be the performance.

In applying this established rule that high total resistance in the lamp is desirable in any case, certain limitations were met with, for example, in adding lamps in series, a point is ultimately reached requiring a current of so high electromotive force as to be dangerous to handle; but in the multiple arc arrangement, there being no increase of electromotive force, as in the case of the lamps in series, the resistance of the individual lamps may be made much higher. The principle can here safely be carried out to the uttermost, making the lamp of as high resistance as possible, but even then limitations were reached. One of them is that material cannot be manipulated to get an exceedingly high resistance, and yet keep down the radiating surface; but nothing in all that militated against the general proposition that from the beginning it had been a recognized principle that high total resistance was desirable, no matter how the lamp was to be used. A parallel case was that of Morse, who, although he had devised an apparatus for transmitting signals by electricity, sending impulses through the low resistance coil that surrounded his magnet, found that if this was placed near the battery his signals were recorded, but, if he interposed a long wire between the battery and his receiving instrument, he was not able to get a signal. Why? Simply because the resistance of his magnet, the working part of his circuit, was not high enough relatively to the other parts. Some one said "Put in one of Henry's high resistance magnets, with a large number of coils of very fine wire, making the resistance of that part of the circuit high relatively to the other parts, and thus concentrate the energy of the current at that point," and the work was done. If it is desired to do work of any kind, put a relatively high resistance at the point where the work is to be done. In that respect there is no mystery in electric lighting. It is on a par with all the other domains of applied electricity in which work is to be done. These principles were perfectly understood in applied electricity, and the man engaged in producing electric light in the year 1878 who had not applied those rules, would have written himself down as one not skilled in the art.

Gen. Duncan said he would next consider the prior state of the art, for it was only thus, of course, that it could be determined what the real invention was to which the claims of the patent relate. Of course it was desirable to ascertain Mr. Edison's date of invention. His own testimony seemed to be very explicit that it was October 21st, 1879. He would assume that this invention was not broadly for putting a carbon burner into a high vacuum, nor for a very slender burner in a high vacuum independent of the material, for these were old in the art. The question was, when did Mr. Edison invent the lamp which depends for its virtue upon that particular form of carbon to which he has given the undefined and undefinable name of "filament?" Not before the 21st of October, 1879. He then read extracts from Mr. Edison's testimony tending to confirm this assumption as to the date of the invention.

Gen. Duncan said that one of the first things to which he desired to call his honor's attention was the Geissler tube. In a general way the Geissler tube consisted of a hollow vessel of glass exhausted to a high vacuum; electrical conductors are passed into the tube and sealed by fusion (Several specimens of different forms of Geissler tubes were handed up to the court). He called attention to Mr. Edison's French patent of June, 1879, in which was illustrated and described an incandescent lamp, which was simply a Geissler tube. Mr. Edison, therefore, himself, recognized, as among the incandescent lamps of the world, a Geissler tube. This Geissler tube shows a receiver made entirely of glass, in the language of the second claim of the patent. It shows also fine platinum wires conducting the electric current into a highly exhausted chamber. These features of construction appeared elsewhere in other instruments that came into the art later than the Geissler tube. Faraday's *Chemical Manipulation*, published in 1831, describes, with great minuteness, how to manipulate the blow pipe, the wire and the glass, in order to accomplish this result. He would next consider briefly Crookes' radiometer, described in articles in the *Philosophical Transactions* of the Royal Society, from 1874 to 1878. One form of radiometer, described by Crookes, was the Edison lamp of the patent in suit, with the exception that they had not got, so far as he knew, the carbon filament. He did not know what the carbon filament was, but evidently it was not in this instrument, because there was no carbon. But there was the high vacuum, the all-glass globe, the fine platinum leading-in wires, and the burner inside. Now that was a lamp: not a lamp intended for general illumination, but for certain special uses. But it nevertheless embodied in its construction principles which Mr. Edison professes to have discovered and embodied in the lamp he devised for general purposes of illumination.

Gen. Duncan then referred to another part of Crookes' paper, from which he drew the conclusion that Crookes had found, that if in a chamber made of two pieces of glass, united by a mechanical joint, a high vacuum could not be maintained, fusion must be resorted to, and one part sealed to the other; so that it might be said the walls were made entirely of glass. He also referred to the testimony of Dr. Adams in the present case, as showing that he had employed the same expedient ten or twelve years before Edison began working in this direction. He would also call the attention of the Court to the record of the application for a patent in 1881 by one Freeman, in which the applicant showed an incandescent lamp having a carbon burner enclosed in an all-glass globe, highly exhausted, with platinum leading-in wires. Freeman was put into interference with this very patent of Edison; one reference cited against him was King's English patent. He then amended his claim to read as follows: "An electric lamp for giving light by incandescence, consisting of a strip or filament of carbon of high resistance enclosed within an exhausted receiver made entirely of glass, and attached to metal wires passing through, and sealed into the glass, as set forth." The Patent Office next cited as a reference Crookes' radiometer, and said: "It is not deemed material that applicant claims a carbon filament in place of the platinum conductor shown in the reference. *The substitution of one for the other being a matter within the skill of one well versed in matters pertaining to electric lighting*, it being old in the art to use carbon conductors for incandescing lamps." This action was reaffirmed on reconsideration, and the application finally rejected. Apparently this publication of Crookes was not known to the Patent Office when Mr. Edison's application was allowed. Certainly it would have been as pertinent a reference against Edison's application as against Freeman's. He would pass next to the consideration of the English patent of King, of 1845. This patent speaks of two kinds of lamps, one of a thin strip of platinum and one of a thin plate or small pencil of carbon. The patent goes on to describe how thin the platinum should be; so thin that by holding it before a printed page the letters could be read through it. So the word "thinness" with King, meant thinness, just as with his friends on the other side, a "filament" meant a filament; and that is about as far as they had got in the definition. It is a "filament" they tell us, because it is not a rod; and it is not a rod, they say, because you can see that it is not a rod. King goes on to say: "When carbon is used it becomes necessary, on account of the affinity this substance has for oxygen at high temperature, to exclude it from air and moisture. To accomplish this in the most perfect manner, it should be enclosed in a torricellian vacuum." Elsewhere he says: "As carbon will bear a very high temperature without fusion or volatilization, it may be employed when a very intense light is required." Here is a recognition, at this early day, of the superiority of carbon in this important particular over platinum. Again he says, "When the apparatus is *suitably sealed* it may be applied to submarine lighting, and also to the illumination of places where it is necessary to guard against the inclination of highly combustible or explosive compounds, as in powder magazines, mines, etc." The defendant's witnesses say that "suitably sealed" means that it must be sealed in such a way as to make it a portable instrument. Professor Brackett, who was brought forward to contest this view of defendant's experts, when asked whether it would require any invention to seal a platinum wire into the glass for the lower connection in the same manner as the upper wire, answered that it probably would not.

What were the things specially sought by the patent of King? These: That carbon had peculiar properties adapting it specially to use for the burners of incandescent lamps; the protection of the carbon from deterioration by enclosing it in the most perfect vacuum which could be made; the necessity of making the burner of very small cross-section in order to secure a high total resistance; and that when platinum wire passes through glass it is to be sealed in by fusion. Referring next to the Roberts-English patent, he stated that the patentee speaks of the burner as a piece of "very thin graphite," "as thin as can conveniently be made," and that "as perfect a vacuum as can conveniently be made must be obtained," and observes that "if the vacuum be perfect no combustion will ensue."

The next important thing was the Edison platinum lamp. Early in 1879 Edison produced a platinum lamp strikingly like the carbon lamp of the present patent. He made an application for a patent in the United States in April, 1879, and almost contemporaneously made application for foreign patents. The French patent issued in June, 1879; the American patent not until May 4, 1880, being therefore later than the patent in suit; but the invention had entered into the art before the making of the invention of the patent in suit, for it had been described in newspapers and crystalized in foreign patents. Handing a copy of the French patent to his Honor, Mr. Duncan pointed out that there was the highly exhausted glass chamber made entirely of glass with two platinum leading-in wires sealed into it by fusion, and connected in the exhausted chamber with a great length of very fine platinum wire coiled on to a bobbin. The American patent says that the function which high resistance plays, is "to enable a large number of lamps to be used in multiple arc," which his Honor would not forget was set forth by the plaintiff as an important feature of this discovery. Gen. Duncan then read a long extract from the French patent, and pointed out that therein was fully set forth the relation which should exist between the size and proportions of the burner of the incandescent lamp, and the quantity of material necessary to be used in the outside circuit for conveying the current to the lamp. What was true in relation to a lamp having a metallic burner was no less true in relation to a lamp having a carbon burner, and whenever Mr. Edison or Lane Fox, or anyone preceding them, had announced that principle, there could be no invention in subsequently applying it to lamps employing a different material for a burner. It became a mere question of electrical engineering. He understood the gentleman who opened for the plaintiff to put forth, as the great distinguishing feature of Edison's invention, that he was the first man to "appreciate" (that was the word he used, not once but a dozen times), he did not even say to "discover," but that he was the first man to "appeciate," at its full value, the relation that high resistance joined to small radiating surface sustained to economy of copper in the conductors. Therefore, he says, the patent in suit is to be sustained with a broad interpretation. "We say," said Gen. Duncan, "that that principle is old in the art." Edison knew it. He had given it to the world—perhaps supposing himself to be the discoverer of it—through various patents, long before he made the invention, which alone can be found in the patent in suit; months before "the great flood of sunlight came upon the art of incandescent lighting" (to borrow his own expression) he had not only described this thing, but had taken a patent for it.

A significant fact bearing upon this point is revealed by an examination of the proceedings in the Patent Office relating to this platinum lamp patent. When that application was filed, it contained this claim:

"In combination with a sealed vacuum chamber made entirely of glass a continuous incandescent *metallic* conductor as set forth."

After the allowance of the patent in suit, Mr. Edison substituted for the claim just read, this one with which this patent issued:

"In an electric lamp, the combination with a hermetically sealed vacuum chamber made entirely of glass, of metallic conductors passing through the glass and around which the glass is melted, and an *incandescent* conductor placed in the electric circuit, substantially as set forth."

The word "metallic" has disappeared from the incandescent metallic conductor of the original claim. That claim was broad enough to include all sorts of burners, whether made of metal or of carbon, or of any composition of matter; it was so intended. Prof. Barker testified that it is a broader claim than any claim of the patent in suit. Now, what was the meaning of it? After having secured the allowance of the patent in suit, they take this earlier application, elaborately setting forth the theory of the relation of high resistance plus small radiating surface to the wires of the circuit, and insert a broad claim that will cover both carbon and platinum lamps. If they have any patent on that subject matter it is No. 227,229, the platinum lamp patent and not the patent on the carbon burner. The full significance of that change was that whatever plaintiffs might think to-day, at that moment they could not have regarded the carbon patent as covering this principle of electrical engineering. It was not patentable at that date to any human being. It was as free as the air we breathe or the sunlight that beams upon us. His Honor might be interested to know why suit was not pressed on patent 227,229. That patent was in suit once, but was withdrawn by reason of a certain adjudication on the Bate patent in the Supreme Court. He supposed, at least, that that was the explanation, but at all events, that patent was originally made part of the subject of controversy in this cause; and the language of the bill glorifying Mr. Edison for his great work in this art is to be read in connection with that patent—wherein he has undertaken to patent a problem in electrical engineering—as well as in this one, in which he has coiled up a little piece of tar-putty, stuck it into a globe, and said "that is a great invention too." They might be met with the question whether the platinum lamp was a practical lamp. He did not feel called upon to answer that question, but was free to say that it had not obtained commercial use; it had quickly been followed by better lamps. Nobody questions that carbon is a better material than platinum. Mr. Edison and others had found that out, and it had been known beforehand. There was a difficulty in manipulating carbon to get a sufficiently high resistance. A wide field was open there for all inventors, and when one man found one method, and another another method, of taking carbon and bringing it into a filamentary form and having it stand, then lamps were made that were better than platinum lamps and that are in use to-day. The great field for invention then opened for the world was, how to make a burner that would satisfy the necessary engineering requirements. If Mr. Edison could make a high resistance carbon burner by rolling lampblack and tar into a fine wire and carbonizing it, he was entitled to a patent, if it was new. If it was better adapted for wide distribution by coiling it into a close spiral, for that also he might have been entitled to a patent. What he was contending for, however, was this great principle—which gentlemen propose to credit to Mr. Edison—of the relation between high resistance and small cross-section of the burner, and the amount of copper required to carry the current from the dynamo to the lamp, was not and could not be a part of the patent in suit. Gen. Duncan then cited the Khotinsky French patent of 1875 and the American patent of Woodward in 1876, as showing arrangements of incandescent lamps in multiple arc. He then passed to the consideration of the Lane-Fox patent and pointed out that it revealed, as fully as Edison's French patent, the relation between high resistance in the burner and the amount of copper required in the conductor.

Referring to the work of Sawyer and Man, Gen. Duncan said, that early in 1878 they were engaged in the development of a system of incandescent lighting; they operated with small carbons less than a millimetre in diameter, some of them but $\frac{1}{64}$ of an inch in diameter. The principal point in connection with them was, that the material was shaped before carbonization, and that they were exceedingly small—much smaller in cross-section than many of the commercial lamps of the present day. Summing up the prior state of the art, Gen. Duncan contended that the utility of carbon as an incandescent burner was well-known; so was the utility of the high vacuum to protect the carbon; so was the desirability of making the receiver entirely of glass; the use of fine leading-in wires of platinum; the arrangement of lamps in multiple arc; the necessity of giving the burner a high total resistance in order to secure wide distribution in multiple arc; the idea of making the burner of small cross-section; the manufacture of carbons by carbonizing a mixture of lampblack and tar. There were other things not explicitly described, perhaps not more than hinted at in these earlier patents and publications, which are found in Mr. Edison's patent, for instance, the securing the carbon burners to the leading wires by carbonizable plastic cement.

This appeared to be new with Mr. Edison. He had got a thing which he calls a "filament" but he had not defined it. He says it is so fragile it cannot be clamped; therefore he had to devise a new mode of securing it to the leading-in wires, and that seems to be one of the essential things of the filament. He also speaks of the filament as being made from carbon of high resistance. It is assumed from Edison's own testimony that that means a carbon that is purely structural. That is a carbon, the product of carbonization, made without subjecting it to any process that would reduce its specific resistance. The extreme importance of this distinction would be seen further on, for defendant's carbons are treated so that their specific resistance is vastly lower than that of purely structural carbon. In Edison's English patent, 3,765, of 1880, is found the following: "The practice, so far as known, has been to make them of as low resistance as possible, that is, low specific resistance—a porous carbon having been used which was dipped or soaked in some carbonizable liquid until its pores were filled, and then subjected to recarbonization, which process was repeated until the pores of the original carbon were filled with carbon. By this process the resistance of the carbon is lessened while its liability to disintegration under high heat is increased." Now, note that he says: "*Such carbons are unfit for use in electric lamps giving light by incandescence.* For such lamps, said Edison has discovered that the incandescing material should have the highest possible resistance in very small bulk, and be capable of resisting the disintegrating effects of very high heats and the absence of atmospheric pressure," and further that "*carbons which are purely structural in character alone possess these qualities.*" By "purely structural" is meant a carbon wherein the natural structure, cellular or otherwise, of the original material is preserved unaltered; that is, not modified by any treatment which tends to fill up the cells or pores with unstructural carbon, or to increase its density or to alter its resistance." Now, if that is the kind of carbon from which Mr. Edison in this patent proposes to make the burners of his lamps, they were not disposed to contest the novelty of his invention. Another possible feature of novelty disclosed in the patent in suit is the use of a carbon of a total resistance of 100 ohms. They did not think there was anything patentable in that, but stress seemed to be laid upon it in the patent. There were at least half a dozen statements in evidence by Mr. Edison, that at least 100 ohms were essential. It was assumed, therefore, that he intended to limit himself to that as a minimum; and so far as a carbon burner was concerned, that—for all that appears to the contrary in the record—was novel with Edison, even if not patentable. Another feature on which great stress was laid, the novelty of which they were not disposed to contest, was the coiling of the thing called a filament into a close spiral, so that only a portion of the external surface should have an active and efficient radiating surface. The prior state of the art did not show that this method of manufacturing the burner of an incandescent lamp had been resorted to. Mr. Edison dwells upon it with emphasis as performing a very important function. He was not asserting that it was patentable, but that it was the first time the thing had been distinctly announced. There had been a coiling of platinum, but it had not been stated that it was for the purpose of diminishing the radiating surface.

Certain points were formulated by Prof. Barker as important elements in the invention of the patent. He credits Edison with making a new departure in the art embracing the following features: (1) The carbon burner with small cross-section and small radiating service, even when of considerable length; (2) a filamentary burner of porous carbon of high resistance; (3) a filamentary burner first formed and then carbonized; (4) an all-glass bulb as distinguished from a separable chamber with cemented joints. As to the first feature, Gen. Duncan contended that it exhibited no invention. Prof. Cross says the value of the principle is wholly independent of the material of the burner, and had always been recognized in the case of platinum. He testifies that it is a mere application of the commonest principles of electrical engineering at that time familiar to those skilled in the art. His testimony is confirmed by Shallenberger, a graduate of the Naval Academy, competent by education and experience to pass upon the question, being familiar with the firing of torpedoes electrically by platinum fuses placed in multiple arc.

He would not say that the questions put to Edison on this subject had been dishonestly evaded, but they certainly had not been met in a frank and manly manner. It had been sought to search the conscience of this inventor; to know whether he really believed he had made a great discovery as to the relation existing between high resistance and small radiating surface and the amount of copper in the circuit. He hoped the court might find time to read every word of Mr. Edison's deposition when called as a witness for the defendant. He read among other extracts the following from Mr. Edison's testimony: *Q.* "Do you consider yourself the discoverer of that relation?" *A.* "I do not consider myself the discoverer of Ohm's law. It will explain all things that have been done and probably every thing that will be done in the next thousand years in electricity." *Q.* "I ask you whether you consider that you are the person who discovered the relation between the size and proportions of the burner and the character of the conductors conveying the current to each lamp, when being used in multiple arc?" *A.* "I do not know whether I am or not in relation to an incandescent lamp. Ohm's law does not mention incandescent lamps. It is a general law." So he went on, and presently began to quarrel again with Ohm's law: *Q.* "Didn't you know as a matter of inference from Ohm's law, that with a given size of conductor it would be necessary to give the individual lamps a higher resistance if they were to be used in multiple arc, than if they were to be used in series?" *A.* "It is not necessary in applying Ohm's law at all, but when you bring in the commercial element, then it is; *the fact of the matter is, that at the time I experimented on the incandescent lamp I did not understand Ohm's law.*" *Q.* "Do you mean that you did not know the formula of Ohm's law at that time?" *A.* "No, sir; I did not know it." *Q.* "When did you first get knowledge of Ohm's law?" *A.* "*It may seem strange for me to state that I do not understand Ohm's law to-day.*" *Q.* "I do not ask you whether you understand it, but when did you first know of it?" *A.* "I have heard of Ohm's law for the last twenty years." *Q.* "What do you mean by saying that you did not know Ohm's law at the time you began experimenting with incandescent lamps?" *A.* "*I mean to say that I did not understand Ohm's law. I do not understand it now and I do not want to understand it. It would prevent me from experimenting.*" *Q.* "Why?" *A.* "Because I would try to figure it out mathematically; *I have employed a great many mathematicians; they have all been dead failures.*" *Q.* "Does that include Mr. Upton?" *A.* "Yes, sir, in his mathematical capacity."

His Honor would see that they got no answer to their question. They had put Mr. Edison a fair question, intended to search his conscience, as to whether he believed he was the discoverer of that wonderful relation between the proportions of the burner, and the character of the circuit; the thing which formed the burden of the opening argument; the thing in which the great merit of this invention was supposed to consist, was this relation. They were fairly entitled to an answer to the question. But Mr. Edison flies into a quarrel with one of the great laws of nature; says that he does not understand it; doesn't know, nor want to know, what it is! Were they to believe that he, of all men, did not understand Ohm's law; one of the fundamental laws of electricity taught to children in primary schools? It was incredible. It was his method of avoiding an answer to that question; nothing more. It was a masterly performance in one aspect. When a knot was presented to Alexander which could not be untied, he cut it; so Mr. Edison evaded this question by a method not fair nor ingenious; it stands to-day on the record unanswered. There are other things betraying a similar real or assumed ignorance by Mr. Edison. Judging from his language, he honestly believed when he gave his testimony, that in 1879 he made for the first time the grand discovery that in an all-glass chamber, exhausted by a torricellian pump, a permanent high vacuum could be maintained. For the first time he came to know, what the rest of the world had known for a decade, that there was such a mechanism as a Sprengel pump, and he pats himself on the back, retires behind his own ignorance, and thinks he is a wonderful inventor! He takes his own ignorance as an understanding as to what constitutes invention! On the question of how much invention there was in proportioning the size of the burners and the copper in the circuit, the plaintiff's expert, Clarke, says there are no specific directions in the patent and none were necessary. When asked whether if all Mr. Edison had ever done had been to make, by the process described by the patent in suit, a single lamp, which had proved durable under test, it would have been the practical solution of the problem of the subdivision of the electric light, he answered yes; and why? Because persons skilled in the art would have at once known how to construct other lamps having burners properly proportioned for use in large numbers in multiple arc. Dr. Chandler has also expressed the opinion that mere engineering and mechanical skill was sufficient to adapt the old lamps to rendering them available for use in large numbers in multiple arc. Dr. Barker has said that an important feature of Edison's so-called "new departure" was in shaping the material for the burner before carbonization. But there was no novelty in that. Edison does it here with the plastic material. Carré and others had done that. Dr. Barker, on cross-examination, testified that he had done it himself in 1854. (At this point the court adjourned for the day.)

EDISON ELECTRIC RAILWAY SUIT AGAINST THE WEST END ROAD.

A special dispatch from Boston, of June 10, says:—"Two bills in equity were filed last Monday in the United States Circuit Court for the district of Massachusetts against the West End Street Railway Company, of this city, one by the Sprague Electric Railway and Motor Company and the other by the Edison General Electric Company, for alleged infringements of patents held and controlled by the plaintiff corporations.

"It is stated in the bills that the defendant has been guilty of the alleged infringements for some time past, one date being as far back as January, 1889, and the plaintiffs pray not only for an injunction, but for remuneration for past usage. An injunction will be asked to prevent the West End Company from using, first, the underground wire which is employed to connect the rail so that there may be a better conductor for the return current; second, to stop the use of guard wires; third, to practically prevent the use of trolley and feed wires; fourth, to prohibit the use of motors in parallel circuit, and last, to prevent the cutting of different sections of the line. These features are vital ones in all overhead electric railway systems, and without them cars could scarcely be run at all. If, therefore, the present injunction prayed for is granted, it will seriously affect a great many electric roads all over the country."

It is added in a later dispatch that the Thomson-Houston Co. will defend the suits. On inquiry, the patents referred to are stated to be the Edison patent 273,494, on conductor for reinforcing rails; the Edison "multiple arc" patent 369,280; the Sprague patent 317,235, combination of working conductors and feeders; Sprague patent 328,821, combination of two sets of working conductors with common source for each; and Sprague patent 338,313, working conductors divided into independent sections.

SYLLABUS OF THE OHIO DECISION IN FAVOR OF THE SINGLE TROLLEY.

The syllabus of the Ohio Supreme Court's decision in the case of the Cincinnati Inclined Plane Railway Co. vs. the City and Suburban Telegraph Association, adverse to the telephone and favorable to the electric street car interests, for the use of the ground for return currents, has now been given out, the full text being as follows, the opinion having been prepared by Judge Dickman:

1. The dominant purpose for which streets in a municipality are dedicated and opened is to facilitate public travel and transportation, and in that view new and improved modes of conveyance by street railways are by law authorized to be constructed, and a franchise granted to a telephone company of constructing and operating its lines along and upon such streets is subordinate to the rights of the public in the streets for the purpose of travel and transportation.

2. The fact that a telephone company acquired and entered upon the exercise of a franchise to erect and maintain its telephone poles and wires upon the streets of a city prior to the operation of an electric railway thereon will not give the telephone company, in the use of the streets, a right paramount to the easement of the public to adopt and use the best and most approved mode of travel thereon; and if the operation of the street railway by electricity as the motive power tends to disturb the working of the telephone system, the remedy of the telephone company will be to readjust its methods to meet the condition created by the introduction of electro motive power upon the street railway.

3. Where a telephone company, under authority derived from the statute, places its poles and wires in the streets of a municipality, and in order to make a complete electric current for the transmission of telephonic messages uses the earth, or what is known as the "ground circuit," for a return current of electricity; and where an electric street railway afterwards constructed on the same streets is operated with the "single trolley overhead system"—so called—of which the ground circuit is a constitutent part, if the use of the ground circuit in the operation of the street railway interferes with telephone communication, the telephone company, as against the street railway, will not have a vested interest and exclusive right in and to the use of the ground circuit as a part of the telephone system.

Judgment of the Superior Court at general and special term reversed and petition dismissed.

This decision was given in brief in the last issue of THE ELECTRICAL ENGINEER and commented upon editorially.

STORAGE BATTERY LITIGATION.

In spite of the steps towards a renewal before Judge Coxe of storage battery litigation last week, reports were current as to negotiations looking toward an understanding between the Brush and Electrical Accumulator interests.

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED JUNE 9, 1891.

Accumulators:—

Secondary Battery, W. W. Griscom, 453,695. Filed Dec. 10, 1887.
Consists, essentially, in enclosing the component parts—that is, the positive and negative elements—in a strong, closed chamber. The elements are in the form of masses of dough or paste. The vessel or chamber is divided by a porous diaphragm. The containing vessel is made of strength sufficient to withstand the pressure of the large quantities of gas generated. When the electrolyte is entirely decomposed the battery is operative as a gas battery.

Secondary Battery Element, J. H. Walter, 453,950. Filed Aug. 19, 1890.
Relates to the formation of electrode, which consists of a transversely corrugated metal tape wound or bent upon itself so as to present its edges outermost.

Secondary Battery, S. C. C. Currie, 453,995. Filed Jan. 31, 1891.
The electrode has a metal core or internal conducting body with an integral spongy or porous metallic surface and is inclosed in a covering of woven or braided fibrous material.

Alarms and Signals:—

Engine-Indicator for Steam Vessels, W. E. Hadlock, 453,696. Filed Nov. 14, 1889.
For indicating the movement of the engine and its direction to the pilot or captain of a vessel.

Electric Fire-Alarm, M. M. Braun, 453,723. Filed Feb. 17, 1891.
A thermostat, including a spring contact held open by an inflammable cord.

Fire-Alarm Telegraph, G. F. Milliken, 453 982. Filed Feb. 24, 1891.
A system including, with the usual district alarm boxes, auxiliary apparatus located in private dwellings, business offices, &c., for transmitting an alarm to a central station through the district boxes.

Non-Interference Signal Box, F. W. Cole, 453,993. Filed Feb. 7, 1891.
Relates to the class of non-interference apparatus which requires for its operation a closing of the signaling circuit of longer duration than the longest closing in any signal.

Conductors, Conduits and Insulators:—

Electric Conduit, J. E. Price, 453,733. Filed Jan. 7, 1891.
An underground conduit. A sectional conduit fitted with a lid closing the sections at the top, and capable of removal at any point for the inspection and repair of conductors.

Dynamos and Motors:—

Commutator, E. A. Sperry, 453,822. Filed Feb. 20, 1891.
The commutator contains an elastic medium to relieve the insulation from compression strains due to the expansion or contraction of the parts.

Commutator for Dynamo-Electric Generators and Motors, H. Davis and A. H. Stokes, 453,858. Filed Dec. 11, 1890.
Encloses the commutator bars and brushes in a surrounding atmosphere impregnated with gas to avoid danger of explosion from sparking and to protect the brushes from dust and the weather.

Galvanic and Thermo-Electric Batteries:—

Electric Battery, J. O. Brinkerhoff and M. E. Smith, 453,898. Filed Nov. 26, 1890.
Employs an exciting fluid formed of antimonious chloride and an alkaline chloride.

Lamps and Appurtenances:—

Electric Switch, L. F. Furlong and F. O. Tucker, 453,633. Filed Oct. 24, 1890.
Adapted for incandescent lamp circuits. A quick-acting switch, the operation of which includes the insertion of insulating material between the contacts when separated.

Electric Arc Lamp, J. W. Ells, 453 693. Filed Mar. 21, 1890.
Relates to the class of arc lamps in which the light is produced between the peripheries of two carbon discs. The discs are located in planes perpendicular each to the other.

Manufacture of Incandescent Electric Lamps, R. A. Fessenden, 453,742. Filed Feb, 18, 1891.
Relates to the material of the leading-in wires and to sealing them in the glass bulb. Employs oxidizable leading-in conductors and exhausts the air from the globe before fusing the glass to the conductors.

Lighting of Tables and the like by Electricity, O. H. Stovell, 453,871. Filed Feb. 24, 1891.
Provides channels in the tops and legs of tables for conducting wires, and means for joining the latter to house conductors.

Measurement:—

Electrical Measuring Instrument, F. C. Wagner, 453,681. Filed Dec. 23, 1890.
Relates to the class of meters which utilize the heating effects of a current. Includes two substantially similar and equal wires fixed at their extremities, and mechanically connected transversly so as to act in opposition to each other.

Miscellaneous:—

Electric Cigar-Lighter, H. B. Brown, 453,618. Filed Dec. 5, 1890.

Billiard Table, L. A. Spaulding, 453,674. Filed Mar. 7, 1891.
Electric push-buttons arranged to respond to the weight of a ball.

Phonograph, T. A. Edison, 453,741. Filed July 30, 1890.

Distributing-Frame for Electric Conductors, A. S. Hibbard, 453,863. Filed Feb. 28, 1891.
For the disposition of connecting wires between the main conductors or cables leading to the streets from a telephone exchange and the office cables leading to the switch-board.

Electric Switch, W. Mitchell, 453,888. Filed Jan. 8, 1891.
Designed to provide means for extinguishing a spark or arc. Also provides means for combining the current from two sources at will in one circuit.

Railways and Appliances:—

Electric Railway, J. Jones, 453,710. Filed Jan. 15, 1891.
Relates to trolley-crossings.

Supporting and Connecting the Driving-Motors of Electric Cars, S. H. Short, 454,008. Filed Nov. 22, 1890.
Relates to the suspension from the car axles of a frame supporting the field-magnets of a motor or motors of which the armature or armatures are mounted on and connected directly with a driving axle.

Telephones and Apparatus:—

Attachment for Telephones, E. E. Baker, 453,722. Filed Feb. 17, 1891.
For supporting a writing tablet.

Metallic-Circuit Test and Time Signal for Telephone Exchanges, J. J. O'Connell, 454,016. Filed Oct. 4, 1888.
For determining whether a line called for at one section of a multiple switch-board is connected or in use at any other section.

MR. CHARLES G. ARMSTRONG, the consulting electrician of Adler & Sullivan, the well-known architects, is making plans for an arc and incandescent electric light plant for Wheaton, Ill.

TRADE NOTES AND NOVELTIES

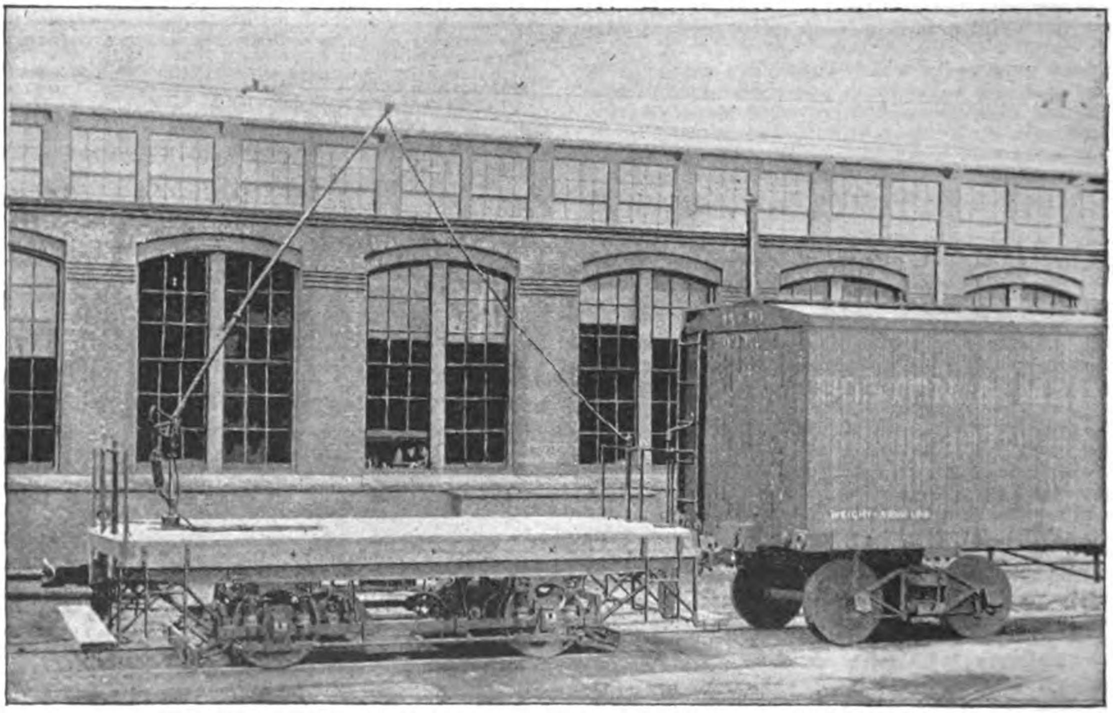
AND MECHANICAL DEPARTMENT.

Let your "ads." do the talking this hot weather.

THOMSON-HOUSTON ELECTRIC FREIGHT CAR.

THE accompanying illustration serves not only to illustrate the apparatus, but in addition proves that almost every day sees the production of some new type of electrical machinery adapted to mill work. The handling of both raw material and finished products of a mill is now rendered an easy matter by the use of the electric current There are but few of the largest mills that have not sufficient surplus power to operate an electric generator, the current from which, by the aid of electric motors, can be made to do certain classes of work much more satisfactorily and economically than can be accomplished in any other way.

The subject of the cut is one of the largest freight locomotives which has been constructed to operate by means of electricity. It was built by the Thomson-Houston Motor Co. of Boston, and is now in use at the cotton mills of the Lonsdale Co. at Lonsdale, R. I. As can be seen from the illustration, the locomotive consists of a platform car and truck equipped with a thirty horse-power Thomson-Houston motor. It is provided with a trolley stand and trolley at one end, and at each end with a controller stand by means of which the speed of the locomotive can be governed and its direction changed when necessary. The locomotive is capable of hauling a load of 60,000 pounds at the rate of five miles an hour. In addition to its use for haulage purposes, the locomotive platform, which measures eight by eighteen feet, may be loaded with material which it is desired to transport from place to place.



THOMSON-HOUSTON ELECTRIC FREIGHT CAR.

The total length of track over which the locomotive is used is 2,700 feet, on which the single overhead trolley system has been used, the wire being suspended over the centre of the track by means of brackets fastened to the buildings where possible, and to poles. The conductor varies in height from the ground between sixteen feet and eighteen feet. The necessary electric current for the operation of this tramway is obtained from a 500 volt Thomson-Houston dynamo of 30,000 watts capacity, which is driven from one of the water wheels which furnish power for the mill machinery.

MR. CHAS. D. SHAIN, general manager, eastern district, of the Edison Co., spent several days visiting his agency in Washington during last week.

DECORATIVE ARC LIGHTING.

Although the arc light has been in use a great many years, it cannot be said that it has developed as many features of beauty as of utility. At one time it was expected that the arc light would lend itself readily to schemes of decorative illumination, but such hopes have generally been disappointed, and but too often that which should have been a thing of beauty and a joy, has been a positive eyesore, either through the clumsy and ugly construction of the lamp or because while neat and trim at first the lamp has been allowed to become dirty and dilapidated. Yet there was nothing very much out of the way about those earlier hopes, and now the success attending the introduction of arc lamps on incandescent circuits leads us to believe that these optimistic views of the case will be amply justified. At any rate, the Universal Arc Lamp Co., of the Edison Building, Broad street, recognizing the great possibilities of the situation have, for some time past given their attention to this very matter, and they have already found that they have not overestimated the importance of the field or the urgency of the demand. They are now making a specialty of decorative arc lighting. In other words, not only do they offer and design ornamental arc lamps to go upon the incandescent circuits, but they also make such lamps in new and novel designs and finish, so as to harmonize with styles of architecture or with any kind of interior decorations and furnishings. A peculiar merit of the Universal lamp is that it can be hung at any angle without in any way losing efficiency, and will burn most successfully in positions that only an incandescent lamp had been supposed to be capable of assuming. The company is to be heartily congratulated upon this new departure, which is destined to give the public a very favorable idea of the flexibility and beauty of electrical methods of illumination.

After prolonged competitive tests in the New Jersey Central Depot, the Universal lamp has been finally accepted, and the company looks upon this result as a very good indication of the merit of its lamp. Another step forward is that made by the company in placing ten of its lamps in series across the circuit of one of the largest street railway companies. The steadiness of the lamps under such conditions was remarkable, and the successful trial seems to open up some large fields of use that had not before been comtemplated or, if considered, thought to be impracticable.

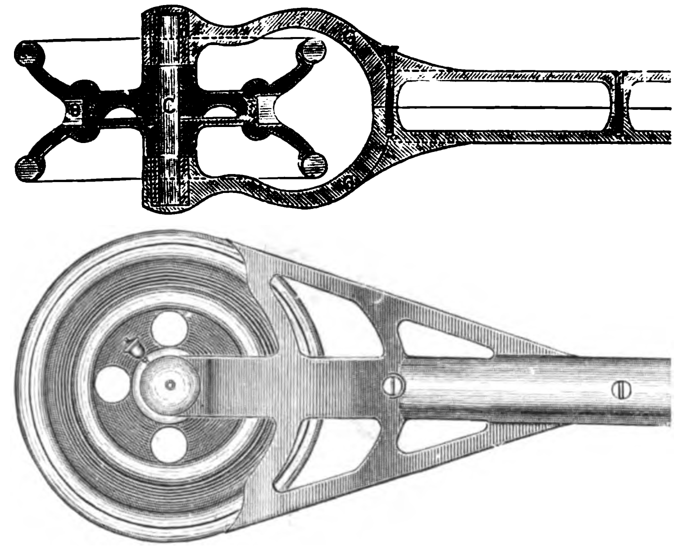
THE RUSSELL ELECTRICAL MFG. CO.

The above company, of Providence, R. I., will hereafter be conducted by Mess. Charles W. Russell and John Heathcote, Mr. John I. Drake having withdrawn from active interest in the concern. They now have large and excellent facilities for manufacturing, and will turn out more and better work than ever before. Mr. C. W. Russell is manager, and Mr. John Heathcote, who is a man of standing and means, is treasurer.

KIMBLE'S ELECTRIC RAILWAY APPLIANCES.

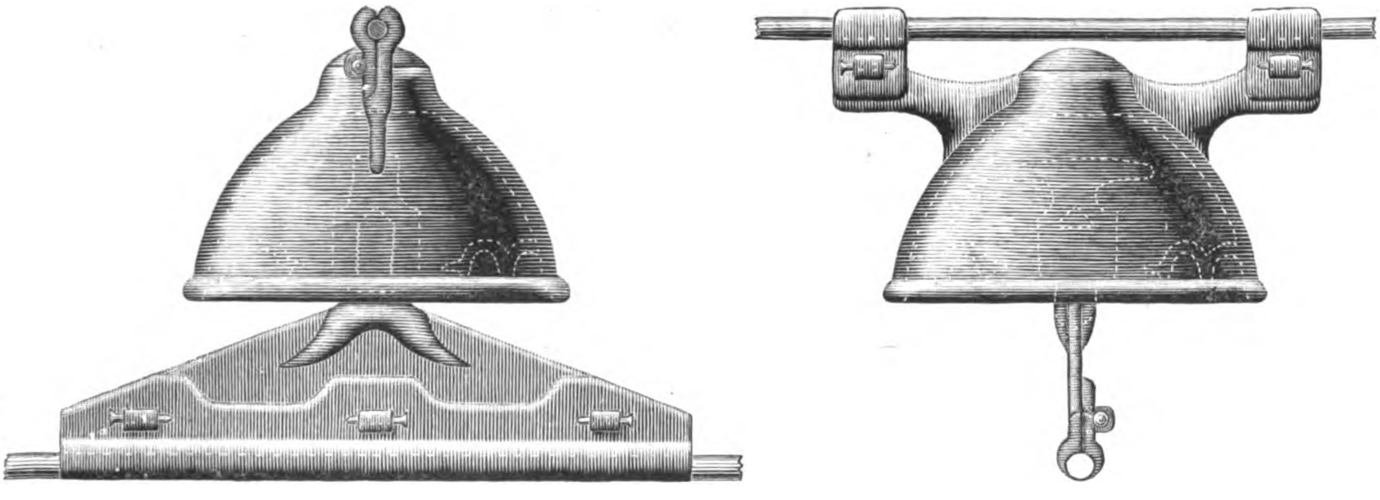
THE wide and constantly increasing field afforded by electric railway work, has led the Mica Asbetite Insulating Co., of Denver, Col., to give special attention to this branch of electrical industry.

The insulating material used by this company is a compound, of which atomized mica is the foundation, and which, while resisting both fire and water, is claimed to be unexcelled in durability.



FIGS. 1 AND 2.—KIMBLE'S SECTIONAL TROLLEY WHEEL.

In the accompanying illustrations, Figs. 1 and 2 represent a novel trolley wheel and holder. As will be seen, the pieces E and F screw together, firmly holding the centre wire bearing, B, which is quickly replaced when worn out. The wheel is firmly mounted on the centre shaft C, which runs in the removable bushing, D, and is lubricated by the oil cup seen in Fig. 2. The shape of the holder prevents the span wires from being caught and broken by the trolley, when jumping from the wire. The rubber tires, A, protect the insulated bells from being broken by the wheel. The holder is in two parts, G, G, fastened together by two screws, and holding all the parts securely in place.



FIGS. 3 AND 4.—KIMBLE'S INSULATED BELL AND COMBINATION CLAMP.

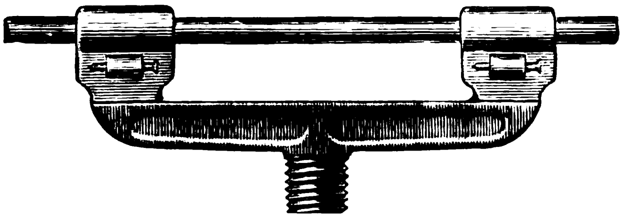


FIG. 5.—KIMBLE'S DETACHABLE CLAMP.

In Figs. 3 and 4 is shown the insulated bell and combination clamp. The insulating compound is hermetically sealed, and holds a button into which the clamp is screwed. The trolley wire is firmly gripped between the two pieces of the clamp, which are held together by three keys driven through the lugs. The clamp can be easily attached or removed by an ordinary tack hammer. In connection with the new form of bell, the clamp shown in Fig. 5 is used, and has the advantage of being easily and quickly detachable.

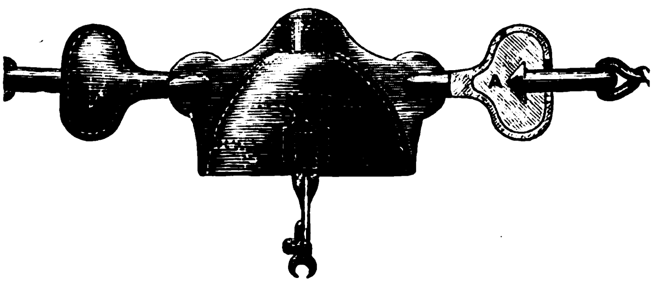

FIG. 6.—KIMBLE'S COMBINATION TROLLEY WIRE HANGER AND STAY.

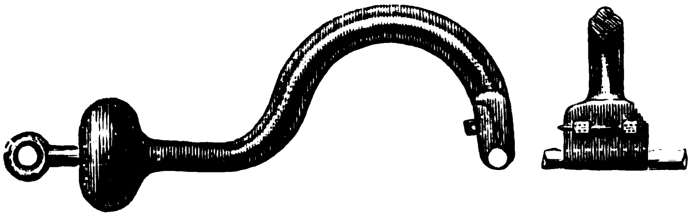

FIG. 7.—KIMBLE'S INSULATED PULL-OVER.

The combination trolley wire hanger and stay is shown in Fig. 6. The insulating hooks and bells are the same as used in staying wires on single track roads. This method combines the hangers and pull-overs in one arrangement, and also effects a double insulation.

Fig. 7 shows the insulated pull-over, or curve bracket. By this device the trolley wire is quickly fastened in place by driving a key through the lug. The button is held firmly by the insulating compound completely insulating the trolley wire.

BERLIN IRON BRIDGE CO.

The Companhia de Foejas e Estaleiros of Rio de Janeiro, Brazil, have placed the order for a large iron building, to be used in connection with their ship building plant, with the Berlin Iron Bridge Co., of East Berlin, Conn., and the order for the machinery with J. A. Fay & Co., of Cincinnati, Ohio. The building will be entirely of iron, 165 ft. wide by 300 ft. long, and will be shipped by steamer from this country, the parts being carefully marked so that it can be erected in place by native workmen at Rio de Janeiro. The Berlin Iron Bridge Co. are doing a large trade with the South American Republics, arising from the closer commercial relations.

PASS & SEYMOUR.

The demand for the porcelain goods of this house is so great that they have decided to increase their plant. In a letter to us, dated June 6, they say:

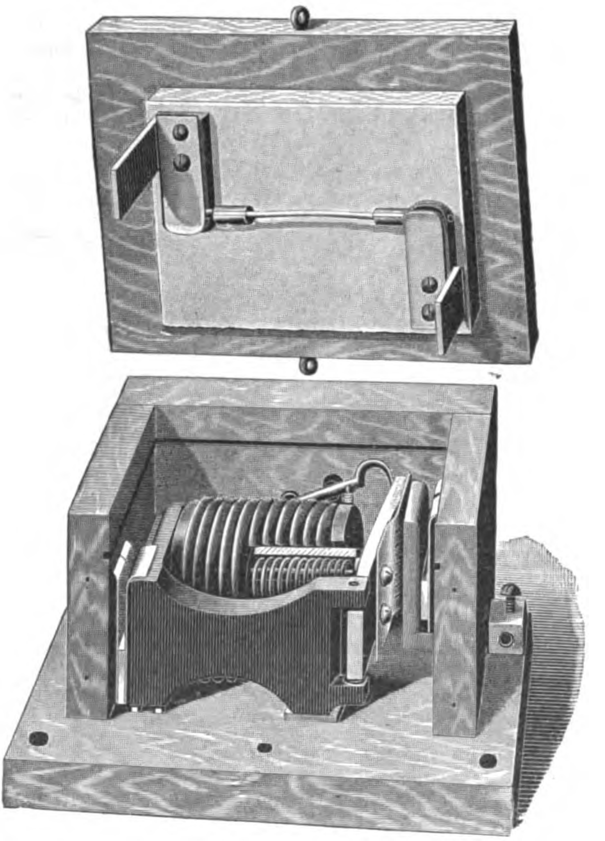
"The fact is, we are so crowded with work that we are doing very little with the line of supplies we intended manufacturing and placing on the market ourselves. Our standing orders are for more than 50,000 pieces per week, and we are actually furnishfrom 80 to 100,000 pieces every week, with telegrams coming in asking when we shall ship, and threatening to countermand unless immediately satisfied. We are contemplating an increase in our plant, which will be an absolute necessity even if our present business continues, to say nothing of an increase."

"We receive many inquiries through our card in your columns, and would not be without it if it cost as much again."

CUTTER'S MAGNETIC CUT-OUT.

ONE of the largest items of expense in many electric plants, and especially in railway systems is the cost of repairing or replacing burnt-out armatures and field coils. In motor cars the whole current may be thrown on before the armature gets up its normal speed, and the burning out of the coils is sure to follow unless there be some reliable safety device. Such a device should be accurately adjusted to open the circuit as soon as the current exceeds its safe limit.

This cannot be done with an ordinary fuse whose carrying capacity is sure to change after current has been passed through it for some time. But by combining a small fuse with a magnetic shunt, we get a device which is as sensitive as it is positive in its action. As the cut shows, the fuse has the current shunted around it through a magnet of low resistance. This is adjusted so as to cut itself out when the current becomes too strong. and send the whole of it through the small fuse. As the current may be ten time the capacity of the fuse, this is sure to blow and thus open the circuit. Another fuse can be quickly slipped into place without the use of any tools, and the cutout is then reset for action.

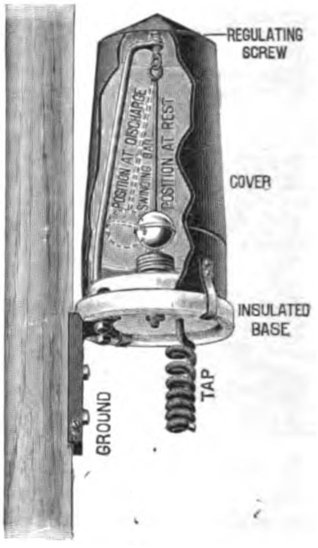


CUTTER'S MAGNETIC CUT-OUT.

The device is qnite simple and the cost of equipping a line with these cut-outs is often less than the price paid for armatures burnt out in a single day. For this reason railway men will be quick to see its merits and to protect their motors with such cut-outs. George Cutter, of Chicago, has developed it and will supply it to stations east and west.

THE SWINGING BALL LIGHTNING ARRESTER.

THE approach of the summer season, accompanied as it usually is by heavy thunder storms, renders it advisable for the central station manager to make provision for the thorough protection from lightning, of his lines and apparatus connected thereto. A lightning arrester, however, ought to embody in itself not only a simple method of carrying the discharge to earth, but ought to be of such design that it needs no attention whatever, so that it is ready to take a series of discharges in rapid succession, and "come up smiling" every time; a requirement which is frequently encountered in practice. To meet these conditions, Messrs. Treux & Vail, of the Electrical Exchange, this city, have just brought out a Swinging Ball Lightning Arrester, which is illustrated in the accompanying engraving. This arrester, it will be noted, is placed directly upon the pole, and connected to the line wire by means of the tap shown. The tap wire, it will be noted, is connected to a discharge terminal secured to the base of the arrester. Immediately above the discharge terminal will be noticed a ball which is suspended from a rod, and is thus free to swing in any direction. The rod suspending the ball is connected to the ground. From the above description it will be clear that a discharge coming from the line is led to the discharge plate by means of the tap, and as it jumps to the ball in its path to the ground, the ball is swung out by the arc to its full limit of swing, and the arc is thus automatically broken. As soon as the arc ceases, the ball returns to its original position and the apparatus is ready for another discharge. The instrument is evidently of the most simple character and requires no expert attention whatever. As an instance of its efficacy, we may note that the Boonton, N.J., Electric Light & Power Co. had, in the past, suffered to a very large extent from lightning, but since the use of the swinging arrester, some time ago, no trouble has been experienced from this source. The arrester has also been in use at Morristown and Elizabeth, N. J., with great success.



THE SWINGING BALL LIGHTNING ARRESTER.

"ISOLATINE" AS AN INSULATING MATERIAL.

There has been recently introduced into the market an insulating material, for which we predict a bright future, which has gradually attracted the attention of some of the best known authorities in the electrical line, notwithstanding the well-known difficulty which a new article of this kind encounters in trying to gain a foothold. The long felt want of a substance combining all the necessary qualities is claimed only now to have been overcome. These qualities are high insulation, flexibility, freedom from change by time and by cold or heat, unless the latter be artificial. Besides possessing the above named qualifications, it has the property of absolutely protecting metal. It therefore would find use in all underground and marine construction work.

It therefore becomes an article which all enterprising wire and cable, primary battery and accumulator manufacturers will investigate thoroughly and hail with delight.

The substance is known as Isolatine, and is brought into the market by the Roessler & Hasslacher Chemical Co. 73 Pine street, New York.

TUBING FOR HOUSE WIRES.

The increased safety secured by running all wires within building in tubes specially provided for that purpose is now so well recognized that their use is specified in the construction of most new buildings, while many with wires now run in moldings or embedded in plaster are being rearranged with tubes.

The manufacture of such tubing for house wires of all descriptions has recently been undertaken by the Eckert Electric Manufacturing Co., of 54 New street, this city, and the company have set a very high standard of excellence for their product. Thus they claim that their tube when held in the flame of a Bunsen burner or gas jet does not ignite and carry the flame, but merely chars, and hence is to all intents and purposes fire-proof. The tubes stand an insulation test of not less then one megohm with a current of 500 volts pressure. The tube is thoroughly moisture-proof and the insulating compound used is not affected by proximity to steam pipes where the temperature may range between 300 and 400 degrees Fahrenheit. Besides their employment for electric light, telegraph, telephone, and other house conductors the tubes are admirably adapted for speaking-tube purposes.

The President of the company, Mr. Wm. H. Eckert, is well known in electrical circles, having for thirty years past been prominently identified with the telegraph and telephone interests in this city.

THE BALL & WOOD CO.

The new plant of the Ball & Wood Company, at Elizabethport, N. J., promises to be a model in equipment and convenience for building the Improved Ball automatic cut-off engines. With a stretch of 900 feet between the main tracks of the Central Railroad of N. J. and Trumbull street, with the Singer Park at one end and the railroad station at the other, it is an ideal manufacturing site. The railroad sidings will serve, one the main machine shop into which it passes, and the other the foundry which, at present, is in contemplation.

From the City Hall in New York to the factory station is exactly ten miles, and a long distance telephone will connect these points, placing purchasers of engines in instant communication with the source of supply. In the main machine shop, even a wide awake engineer will be impressed with the mechanical progress made in the last decate. A glance will embrace an enormous room, light and airy, 70 feet high in the roof, and flanked with wide and substantial galleries sustained by iron columns. Overhead a Shaw electric crane will noiselessly raise a completed compound engine of twenty tons from the testing block, carry it the length of the shop, and place it on a car in readiness for shipment. On either hand are new and massive tools the latest product of shops both East and West, and throughout the entire establishment an air and order of system prevails, which, in itself, will guarantee substantial and excellent work.

It is the intention of the company to increase its plant by adding in length when it becomes necessary, and this can be done without interrupting the work in progress. A number of orders for the Improved Ball engines are already entered, and in another month the factory will be a busy scene, well worth the inspection of engineers as well as purchasers of this well-known engine.

EASTON ELECTRIC CO.

The Easton Electric Company, located at 45 Broadway, New York City, are the sole manufacturers of the Easton arc dynamos, new Universal arc lamp for arc and incandescent circuits, adapted to any dynamo, and the Easton incandescent dynamos, generators, motors, etc. Plants are installed at Rockland, Me.; Elmira, N. Y.; Lynchburg, Va.; Newark, N. J.; Brooklyn, Whitehall and Coney Island, N. Y.; Denver, Colo.; Chicago, Ill.; Milwaukee, Wis.; Burlington, Ia.; Reading, Pa.; Birmingham, Ala.; Milledgeville, Ga.; Eureka, Kan.; Lee, Mass., and Lakeland, Fla. Testimonials and endorsements of the highest character will be cheerfully furnished upon application. The factory of the company is in Brooklyn, N. Y., occupying two floors of a large substantial brick building on Kent avenue, between Keap and Hooper streets. The establishment is in charge of Mr. William D. Perry, vice-president of the company. Two Easton incandescent dynamos have just been sold; one of them, a 100 light incandescent machine, for the Brooklyn Annex Line, making three used on these boats, and a 250 light machine to go into the new Sound steamer "General Slocum."

The Easton Electric Company are now prepared to enter into an arrangement of a favorable character with a reliable and satisfactory concern, who will undertake the exclusive sale of the entire output of the factory for the United States, and they invite correspondence.

The Hide and Leather National Bank, a new institution lately organized, has elected as vice-president the well-known manufacturer of electric leather belting, Charles A. Schieren, of this city.

NEW YORK NOTES.

The National Electric Co. have been awarded the contract to install all the call bells, etc., at the Cumberland Gap Hotel, sanitarium and casino. The contract is for some 400 rooms, two complete watchmen's clocks, six large gravity drop annunciators, and a signaling apparatus with ten stations distant from the hotel; also a complete fire alarm apparatus.

Mr. Louis Walsh, of the Battery Department of Alexander, Barner & Chapin, reports sales so active that he had to suspend taking orders for the present until the batteries for which he has already received orders can be manufactured. This looks very well for the A. B. C. Battery.

Mr. Thomas Towne, the well-known buyer for E. E. Garvin & Co., has been confined for the last two weeks to his house very sick. He is, however, about again as usual and looks none the worse for his recent illness.

The Oneida Mfg. Co., Oneida, N. Y., are manufacturers of a patent improved drill chuck. Their little Hercules chuck has an unbroken bearing upon the drill shank the entire length of the jaw. The freedom from accident thereby afforded the drill shank together with the immovable hold of the jaws upon it, will in a short time effect a saving in drills sufficient to pay for the chuck. This becomes a matter of considerable interest to the electrical fraternity who will probably find it to their interest to look it up.

The American Electric Exercise Machine Company have taken a store at No. 25 East 14th street, this city, and have issued a "cordial invitation" to all their friends and others to inspect the machine at the above address.

Kolesch & Co., 155 Fulton street, this city, carry a full line of draughting room and engineering supplies. It is the headquarters for the supplies of several well-known electrical firms.

The Thomson Electric Welding Co. have opened an office recently in this city, in charge of Mr. F. B. Tracy, and now have a jobbing welding plant in full operation at the works of the Excelsior Electric Co., on Willoughby street, Brooklyn.

Himmer & Anderson have removed from 20 Vesey street to 128 Chambers street, where they will have increased space rendered necessary in order to keep up with the influx of business. At present they find it difficult to fill orders on hand, but propose to catch up.

PHILADELPHIA NOTES.

Mr. Wm. Hazelton, 3rd, of Philadelphia, has just issued a circular letter to his friends, advising them of his recently formed connection with the Continental Trust & Finance Company, of Philadelphia. Mr. Hazelton is organizing a new department in this company for the handling of electrical securities, which are day by day, as he points out in his circular, becoming of greater and more recognized value on the market. Electric railway and lighting companies will welcome the advent of a new company, or rather a new department of an old established company, to take care of their bonds, and we join Mr. Hazelton's many friends in wishing him well-deserved success.

Walker & Kepler have been awarded the contract for installing a plant for the lighting of the new Empire Theatre and Hotel Metropole, now in course of construction at Broad & Locust streets, this city. The plant will consist of four No. 90 Edison dynamos, and will be one of the most complete theatre plants in this country. The Interior Conduit & Insulation Company's system of tubing will be used throughout the work. The stage switchboard will be the Cushing patent of the most improved type, as illustrated not long ago in **The Electrical Engineer**. In connection with this work there will be used one of the new theatrical search lights, to take the place of the calcium light; also six arc lights for outside illumination. The building will be wired on the three-wire system, and the switches so arranged that either the current from the street or from the dynamo can be used.

Mr. Charles K. Westbrook, manager of the Isolated Light and Power department of the Thomson-Houston Electric Co., reports the following new installations:—Williamson Free School of Industrial Arts—1350 incandescents; Omnibus Company General—300 incandescent; Atlantic City Amusement Co.—300 incandescent and 25 arc; Croft & Allen—250 incandescent; M. R. Muckle & Co.—35 h.p. motors besides several other plants of less note.

The Equitable Engineering and Construction Co., of this city, has the contract to build an electric railway of the "Rae" system for the Athens (Ga.) Electric Railway Company. They are also building a three mile road for the Highland Park Electric Railway Co., of Richmond, Va., which will be operated for a time in connection with the Richmond and Manchester Railway.

Baltimore. The Southern Electric Co. have contracts to equip the Hebrew Temple and the Phenix and Maryland Club Buildings with tubing of the Interior Conduit system.

W. S. Griffith & Co. have just put in operation the four 100 h. p. Mather generators recently installed for the Suburban Rapid Transit Co. at Pittsburgh, Pa.

Mr. Leonard Atwood is the new general manager of the Wenstrom Consolidated Dynamo and Motor Co., of Baltimore, Md., and things are going with a vim and briskness that is perfectly exhilarating. Mr. Atwood was formerly mechanical engineer for Chadbourne, Hazelton & Co., and previously with Stokes & Parrish for five years. This has been an excellent training, and Mr. Atwood fits into his new work as to the manner born. He has the enormous advantage, moreover, of being a thorough mechanic, and thus not only can keep things going, but knows whether the output of the factory is being kept up to a high standard. The Wenstrom Co. are now getting a splendid headway.

WESTERN TRADE NOTES.

The Illinois Electric Material Co. during the past week in their electric street railway department, which is presided over by Mr. E. L. Clark, Secretary of the company, have closed contracts for the line supplies and equipment of 18 miles of road.

Mr. W. R. Mason, the manager of the Electric Merchandise Co. of Chicago, has returned from a short but highly successful trip, during which he obtained some large orders for street railway equipments and supplies.

Mr. Geo. C. DuBois, general inspector of the Interior Conduit and Insulation Co., of New York, was a Chicago visitor last week. This well-known system is finding great favor in the West among architects and builders, and this success is largely due to the energetic work of Mr. H. M. Underwood, the general Western agent of the company, who is introducing the system very largely in this part of the country.

Mr. I. Lincoln, Auditorium Building, Chicago, has made specifications for the complete mechanical outfit of the proposed new German Theatre Building in Chicago.

Mr. Hood, the well-known dealer in electrical specialties at 239 Lasalle street, has just taken the agency of the "Jewel" incandescent lamp, and is now handling these lamps in large quantities. They are giving excellent satisfaction, and combine long life without discoloration, with high efficiency and durability. Mr. Hood has also secured the agency of the Mosher arc lamp for incandescent circuits, and is selling quite a number of these popular lamps.

Mr. E. E. Keller, so well known among the electrical fraternity as the manager of the Chicago office of the North American Construction Co. up to the time of their retiring from business, has associated himself with the Fort Wayne Electric Company with headquarters in this city. The Fort Wayne Co. and Mr. Keller are to be congratulated on the new arrangement.

The McGuire Manufacturing Co., manufacturers of the famous Hubbard trucks, are very busy, and their works are pushed to their utmost capacity. Among their recent orders are East Harrisburg Passenger Railway Co., 20 new steel trucks for the Brill car bodies; Sioux City Railway Co., all their trucks; Toledo Street Railway Co., 28 trucks, this being a second order, making 48 trucks in all; Little Rock, Ark., 28 trucks; Worcester & Spencer Street Railway Co., Worcester, Mass., 10 trucks; Galveston City Railway Co., Galveston, Tex., 10 trucks; Lawrence, Mass., 15 trucks; Milwaukee, Wis., 129 trucks; Cicero & Proviso Street Railway Co., Chicago, Ill., a second order of 24 double trucks; Aurora, Ill., 15 trucks; West Superior, Wis., 10 trucks, and they also have shipped trucks to Springfield, O., Salt Lake, Utah, Omaha, Athens, Ga., Grand Rapids, and Salem, Mass. Their trucks are now in use under the car bodies of almost all the manufacturers, and are giving perfect satisfaction.

Mr. J. R. Burdick, the representative of the H. W. Johns Manufacturing Co., of New York, dropped in at the Western office of **The Electrical Engineer** last week.

ST. LOUIS TRADE NOTES.

Mr. L. W. Arnold, the St. Louis agent for the Thomson Houston Electric Company, has secured a contract for a 3,000 light installation for the Carondelet Electric Light and Power Company, South St. Louis. Three alternators of 1,300, 1,000, and 650 light capacity respectively will be installed at present. The Thomson-Houston Company will do all construction work up to the converters, and the local company will do the secondary wiring. Mr. Arnold has also secured a contract for 3,000 lights for the new Wainwright Building, now being erected at the corner of Seventh and Chestnut Streets; also 18 arc lights for the Rankin & Fritz Machine Co.

Mr. Guido Pantaleoni, Western representative of the Westinghouse Electric Co., reports the sale of electric railway equipments at Salina, Kan., 5 cars and 2 60 h. p. generators; Cairo, Ill., 4 cars and 1 80 h. p. generator; Marion, Ind., 4 cars and 2 80 h. p. generators.

Mr. B. M. Barr, St. Louis agent for the Edison General Electric Company, has removed to Cleveland to conduct the Cleveland agency of the company. Through Mr. Barr the Edison General Co. have lately taken contracts for the wiring for 3,000 lights in the new Security Building, corner Fourth and Locust Streets. The wiring will be laid in "interior conduits." Also 1,000 arc lights for the Consumers' Electric Light and Power Co.

The National Electric Manufacturing Co., of Eau Claire, Wis., have, through their St. Paul representative, Mr. C. A. Daigh, secured a contract for 10,000 lights for the Consumers' Electric Light and Power Co.

The New Meston Alternating Current Fan Motor of the Emerson Electric Manufacturing Co. is meeting with great success. Their factory is working night and day to keep up with their orders, and owing to the overcrowded condition of their factory they have been compelled to open up factory No. 2 across the street.

The St. Louis Electric Supply Co. have removed to 809 Locust Street, where they have more commodious and comfortable quarters. Mr. Scott, President of the company, reports a steady business in all lines of their goods.

The Western Electrical Supply Co. have removed to 619 Locust Street. The company has lately been reorganized, Mr. Chas. Scudder is President, R. V. Scudder, Sec. and Treas., and T. J. Wilson, Vice-President and Manager. Their new quarters are commodious and well located for their prosperous business.

The Underground Electric Traction Company of Mo. has been incorporated with a capital stock of $100,000 for the purpose of developing and promoting underground electric traction devices invented by Messrs. Murname and Sheldon. The officers of the company are David J. Murname, President; Jos. B. Sheldon, Vice-President; G. L. VanBeek, Secretary, and Jas. M. O'Shea, Treasurer.

Mr. B. J. Arnold, consulting engineer of the Western Office of the Thomson-Houston Co., Chicago, was in town this week on his way home from Little Rock, where he has been engaged in planning a 2,000 h. p. station for the City Electric Street Railway Co., Little Rock. The installation will include compound condensing engines, Heine safety boilers, and at present 5 100 h. p. Thomson-Houston railway generators. The rolling-stock equipment will consist of 28 cars, fitted with the new single reduction gear motors. The power station will cost about $95,000.

The St. Louis Electric Power Co. have added an 80,000-watt Edison generator to their power station; also a Russell engine of 150 h. p., two 150 h. p. plain tubular boilers and a Berryman heater. The company have taken the agency for the Eddy Motor Co. and have put in some 15 motors of that type, ranging from 1 to 10 h. p. The arc lighting business of the company has proven very successful from the start.

Mr. P. H. Broughton, a Cornell University man of '90, has joined the forces of the Municipal Electric Light and Power Company, as assistant to Mr. Ayer, the general manager.

WASHINGTON NOTES.

Mr. Geo. W. Silsby has sold an Edison R. R. plant to Raleigh, N. C. Five miles of single track and light car equipments will be used.

The Washington & Arlington R. R., of this city, have opened their subscription books, and are fast finding investors. This is the road which will eventually run to Mt. Vernon, the home of Washington. They are to reach this city by means of a new bridge over the Potomac.

The Washington & Tennallytown R. R. have recently purchased two new generators from the Thomson-Houston Co. They are 150 and 200 h. p. respectively.

Mr. Coldgate, of the Thomson-Houston Co., was in town for a few days this week. He reports business throughout the State of Virginia as exceedingly brisk this summer.

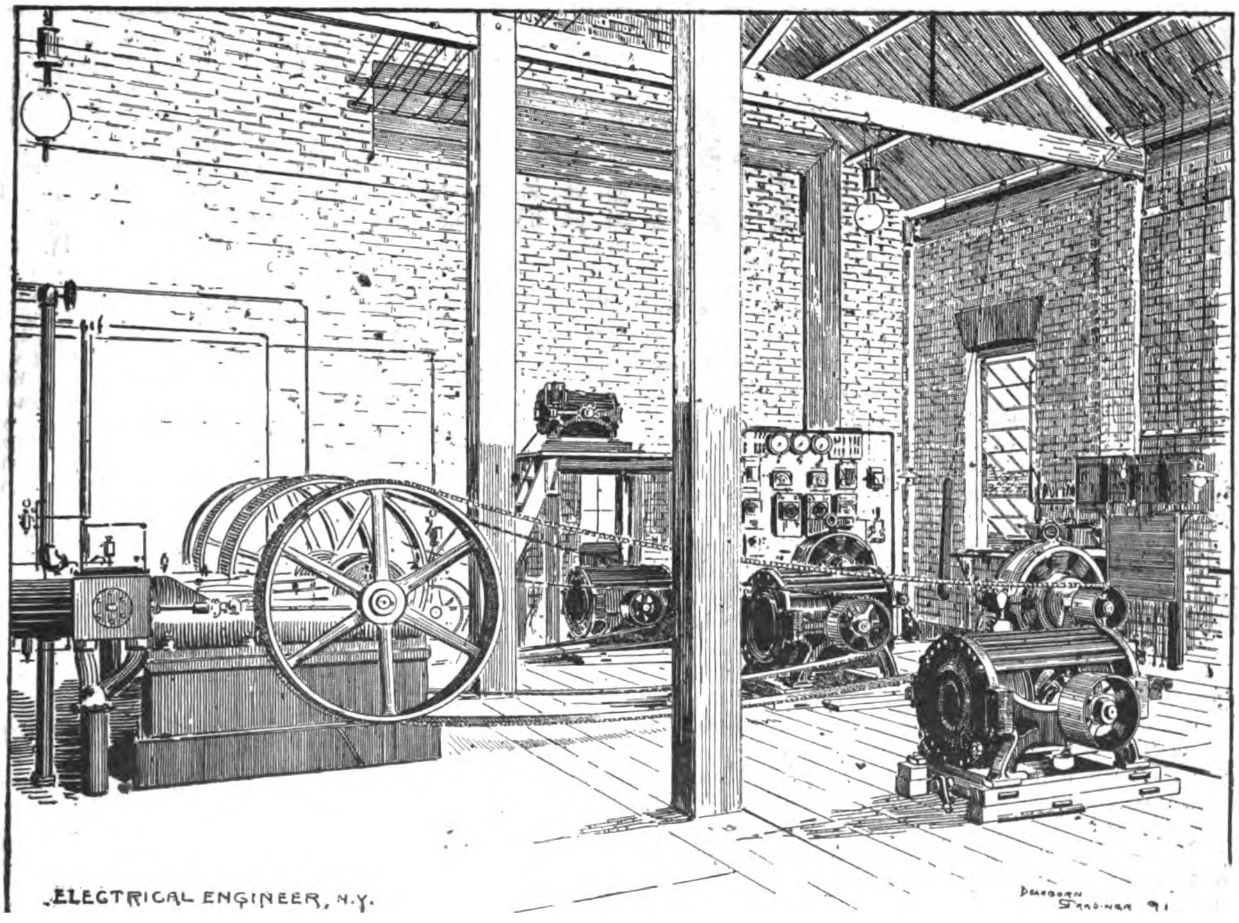
☞ Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Miscellaneous, etc., will be found in the advertising pages.

THE
Electrical Engineer.

Vol. XI. JUNE 24, 1891. No. 164.

KINGSTON ELECTRIC LIGHT PLANT, JAMAICA, W. I.

RECENT experience with hot weather enables all of us to form an excellent idea of the benefits that the electric light confers upon the dwellers in the tropics. Oil lighting and gas lighting are both of them accompanied by many objections in climates where it is no advantage to use methods that combine the lamp and the stove in one piece. Even in moderately warm regions the added heat from oil lamps or gas jets is more than one can steadily endure, and hence we need not wonder at the habit of dwellers in the tropics of sitting for hours in the dark in the open air. There are now very few parts of the globe ignorant of the merits of electricity in furnishing a brilliant light with the minimum of heat, and without smell or fumes injurious to furniture, and hence also we need not be surprised at the rapid introduction of the electric light in places where it is calculated to do the most good. Nor, perhaps, need we be surprised that American apparatus is largely in demand for this special class of work.

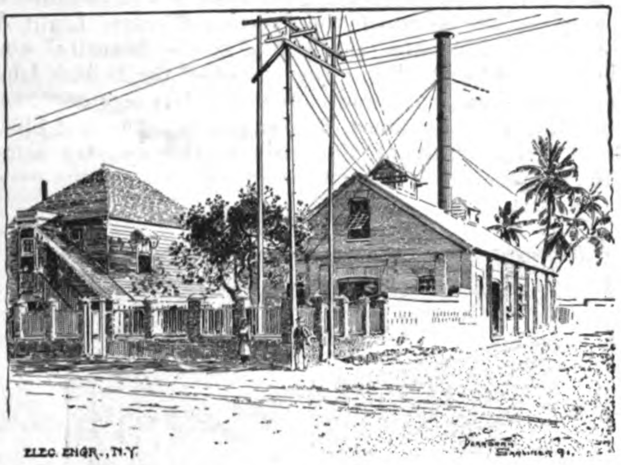


Dynamo Room, Kingston Electric Light Plant, Jamaica, W. I.

A noteworthy exemplification of the success that can be attained in the tropics with a good system well installed is furnished by the plant of the Jamaica Electric Light & Power Co., at Kingston, the capital of the beautiful and productive island which has long supplied the British Isles with choice sugar, rum and coffee, and has now captured our market with the finest of oranges, bananas and pineapples. As a result of the visit to this country some months ago, and of investigations in which it was the good fortune of The Electrical Engineer to assist, it was decided by the new company to buy a plant of American make; and the choice finally fell upon the apparatus of the Thomson-Houston Co., of Boston. A plant was shipped in charge of Mr. G. Montagu White, as engineer-in-chief of construction, and in a very short time the fine station and offices, of which we here show a couple of illustrations, went into successful operation.

The dynamo room seen in Fig. 1 contains two 650 light machines of the alternating system, separately excited, running at 1,000 volts; a 300 light, 110 volts, direct current machine; one 50 light arc machine, one 30, one 9, and one 4. The steam plant at present installed consists of one 120 h. p. McIntosh & Seymour compound condensing engine and one 80 h. p.; with two 125 h. p. multitubular boilers, which are set on the Jarvis plan. The steam plant includes also the latest and most improved condensing apparatus, feed-water heater, purifiers, etc.

At the time the report was made on the plant, accompanying the photographs sent us, the incandescent machines were supplying current to 1,836 lights, but the lighting was of such a mixed character that the load had not exceeded 60 amperes. Orders have been pouring in daily, and the company now intend to add another 650 lighter with a 150 h. p. McIntosh & Seymour engine. Hitherto the dynamos have been run belted direct to the engines, but this arrangement is being altered, countershafting in three sections for the three engines connected by Hill friction clutches being used, and all the dynamos will be run by the Evans friction system. In this way a mechanical combination will be effected equal to a duplication of the old arrangement. The arc machines were carrying a load of 72 lamps.



ELEC. ENGR., N.Y.

KINGSTON, JAMAICA, ELECTRIC LIGHT STATION AND OFFICES.

The company, as will be seen, is already doing a satisfactory business, with the prospect of rapid growth. It deserves mention that the company was able to render valuable service in assisting to light up the recent Exhibition. An English concern that had contracted for lighting the Exhibition was unable to live up to its contract, whereupon the local company was asked for help, and was able to afford it in a very substantial manner.

The construction work of the company has been of the solid, lasting kind, and the street circuits are therefore in excellent shape. Simplex wire was used throughout, so that in every particular the plant is American, a fact that does not lose in significance because Jamaica is a British colony. Whatever may be the political ties of the island, there can be no question that her commercial relations with America become more and more friendly; and it is certainly to the interest of the American electrical industries that this intimacy with so progressive a colony should continue.

THE CASSEL ELECTRO-CHLORINATION PROCESS IN NEW ZEALAND.

According to *Industries*, the Crown Mines Company of New Zealand, a Glasgow enterprise, has made a successful trial of the Cassel electro-chlorination process. A crushing of 263 tons of ore yielded 90½ per cent. of the assayed gold, and 70½ per cent. of the silver. The value of the product was $30.25 per ton of ore, as against $9.75 per ton by the old battery method. The cost of the extraction is set down by the Crown Mines Company as follows: Drying, 36 cents per ton; grinding, $1.22 per ton; cost of Cassel process, $3.16—total $4.86.

FASTENING CIRCUIT WIRES TO ARC LAMPS.

BY

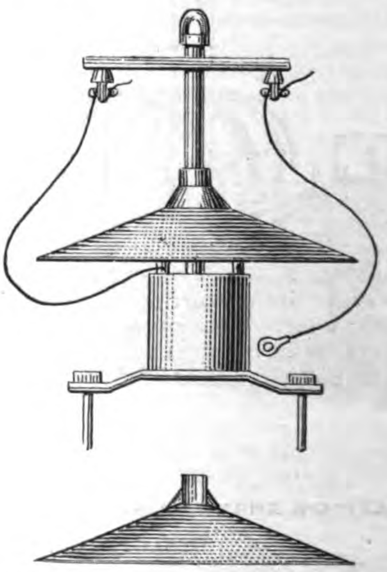
S. H. Sharpsteen

THE president of an electric light company once asked the writer if he was ever bothered with wires coming out of binding posts of arc lamps, and circuits breaking off near the spreaders of lamps that were suspended over the streets and had to be lowered to be trimmed. On informing him that precautions were taken to prevent such accidents he wanted to know what they were.

In the first place our trimmers were instructed to take hold of the lamp wires and wriggle them to see if they were loose, but one asks if that is not a good way to loosen the wires. With the lamps as they used to be made, that is just what a trimmer would do unless he was accustomed to the business. From long experience the writer thinks that for arc lamps in stores, in front of buildings, and suspended over streets the wires should be continuous right into the lamp, not terminating in a hanger-board and from thence to the lamp.

When a lamp is to be put in front of a store, the outrigger or support, hood, and lamp should be as simple and as neat as possibe. Four years ago experience suggested the following to the writer, which was put into practice and found to be very good:

For all outside arc lamps, except those that were put on top of poles under larger hoods, the lamps were arranged as shown in the accompanying engraving. The local tinsmith got us out hoods of galvanized iron, the weight of which we left to his judgment; some were light with wire around edge; others were heavy enough to do without the wire, like the one illustrated, which is twenty-one inches across, with a sleeve at the centre $\frac{3}{32}$ of an inch larger than the horn of the lamp. After the spreader was put on the lamp horn, the hood was put up as far as it would go, and then the horn was wound with insulating tape until the cylinder in the centre of hood would just come down to the position the hood should have on the horn. If the tape is put on properly the hood will fit very snugly. The tape should extend up the horn far enough so that it will project through the sleeve, and the tape should be wound around the top of the sleeve and over on to the tape on the horn.



FASTENING CIRCUIT WIRES TO ARC LAMPS.

If a little care is taken, the hood will be firm on the lamp, water-tight, easily removed, and saves much trouble and expense in soldering. As regards the spreader, it should be made by a carpenter out of good, firm wood 1¼ inch thick. The other dimensions will depend on the size of the hood and the diameter of the horn. It should fit close on the horn and be held in position by tape being wound very snugly around the horn just under the spreader. When the hood and spreader are in place on the horn, all excepting the lower side of the hood should have a good coat of paint.

If the lamp is suspended in front of a building the wires should run from circuit-breaker or pole to hooks in the spreader, and from there around the hood and be soldered into a wire terminal, as illustrated; the terminal should then be put over the binding post and the nut screwed down good and firm on top.

When the lamp is to be taken in for repairs, all that there is to be done is to loosen the wires and unscrew the lamp from the horn; as the lamps should be inter-changeable, another one can be put up at the time the first one is taken down. The arrangement would be similar for a lamp on a cable over the street or on a mast arm.

For inside work, since the fire underwriters will not allow wires carrying high tension current on the wood-work, we run to a knob over the lamp and from there down to terminal or binding post.

ELEMENTARY GEOMETRICAL THEORY OF THE ALTERNATE-CURRENT TRANSFORMER.—IV.

BY

Chas. Steinmetz.

III. Hysteresis and Eddy-currents.

In the foregoing, the loss of energy in the iron, due to the phenomenon of *hysteresis*, and to the existance of *eddy-currents*, was not considered. But even this can be represented easily in the polar-diagram.

The phenomenon of *hysteresis* is in reality nothing but a special application of that law of thermo-dynamics, called *Clausius' Law of Entropy*, which, briefly stated, reads, that all the transformations of energy always take place in such a manner that the sum of the latent heat-energy increases. Hence by the transformation of electric energy into magnetic energy and back again, which takes place in the transformer, a certain part of the energy is always converted into heat.

The *eddy-currents* are proportional to the magnetization; that is, for the field intensities used in transformers—which are always far from saturation—they are about proportional to the resulting M. M. F., F, and they have the same phase as the secondary E. M. F. For they are true secondary or induced currents, with only this difference, that their circuit is not closed by copper conductors, but lies entirely in the transformer-iron.

Therefore these secondary or eddy-currents also exert a certain M. M. F., A, measured by ampere-turns, and this M. M. F., A, is represented, in Fig. 5, by the circle with the line: $\overline{OA} = A$, as a diameter[1] and the phase $\vartheta = 180°$.

Now this M. M. F. *of eddy-currents*, A, combines with the *secondary* M. M. F. L_1 and the *primary* M. M. F. L to the *resulting* M. M. F., F.

Hence F, L_1 A being known, the primary M. M. F. L is found as the last side of the *polygon of sine-waves*, produced by the M. M. F.'s, F, L_1, A.

Or: The primary M. M. F. L and the secondary M. M. F. L_1 must combine by the parallelogram of sine-waves to a M. M. F. $G' = \overline{OG'}$, which, combined with $A = \overline{OA}$ gives the resulting M. M. F. F.

This M. M. F. G', I call the "*electro-magnetomotive force*" of the transformer, because it is the resultant of the two M. M. F.'s of the two *electric* circuits of the transformer.

Thus we derive: *The eddy-currents produce a retardation, that is, a lagging of the resulting* M. M. F. *F and therefore of the magnetism M of the transformer, behind the electro-*M. M. F. *G', by an angle ε.* This retardation can never equal 0, as long as iron is an electric conductor; but it ought to be very small, if the iron laminæ are really insulated from each other.

The angle of this retardation is, within certain limits, independent of the magnetization. For the eddy currents are proportional to the intensity of the magnetism, and therefore to the resulting M. M. F. F, so that $\frac{A}{F}$ is a constant, the tangent-function of the shifting of phase between electro-M. M. F. and magnetism, caused by eddy-currents, being

$$\tan \varepsilon = \frac{A}{F}.$$

But this value of $\tan \varepsilon$ is proportional to the number of periods N, used. For by increasing the number of periods N, that is, decreasing the time of one period T, we proportionally increase the E. M. F. which produces the eddies. Hence we increase the eddies and their M. M. F., proportionally to the increasing number of periods.

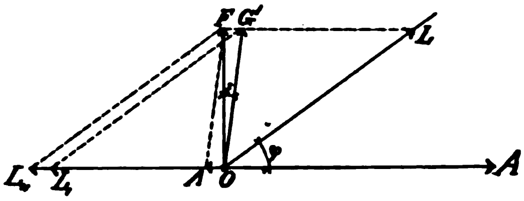


FIG. 5.

For the number of periods, $N = 133$, let the angle of shifting of phase of the resulting M. M. F. F, against the electro-M. M. F. G', be $\varepsilon = 7.5°$ (actual test).

That is, in our transformer, the M. M. F. of the eddies:

$$A = F \times \tan \varepsilon = 320 \text{ ampere turns.}$$

Hence, after having determined angle ε, we draw, in Fig. 6, FL_1, and find the electro-M. M. F. G' by erecting a perpendicular line in F upon $\overline{OF}$, and producing angle $G'OF = \varepsilon$. Then $\overline{OG'}$ is the electro-M. M. F., and connecting G' with L_1 and completing the parallelogram, $OL_1G'L$, we get the primary M. M. F. L, and therefrom, in the same way as in Figs. 2 and 3, the primary current, C, the primary E. M. F. E_0, etc.

Or, we produce, in Fig. 5, line $\overline{OA} = 320$ ampere turns $= .096$ inch as the M. M. F. of the eddy-currents, with the same phase as the secondary E. M. F. E_1. Then the resulting E. M. F., $\overline{OF}$, is the diagonal of the parallelogram, which has $\overline{OA}$ as one, and the electro-M. M. F., $\overline{OG'}$ as the other side. Hence we get $\overline{OG'}$ by producing this parallelogram, $OAFG'$, and from $\overline{OG'}$ and $\overline{OL_1}$ we derive $\overline{OL}$, etc.

Or, in Fig. 5, we combine directly both secondary M. M. F.'s, $\overline{OL_1}$ and $\overline{OA}$, with the M. M. F., $\overline{OL_{11}} = \overline{OL_1} + \overline{OA}$, and from these combined M. M. F.'s and the resulting M. M. F. $\overline{OF}$, we get $\overline{OL}$ by means of the parallelogram: $OL_{11}FL_1$, and from this the other quantities.

When a more exact determination of the eddies is needed, especially for transformers with variable magnetism (constant-current transformer), their dependence upon the varying magnetic conductivity has to be taken into account, as will be shown later on.

Much more complicated is the phenomenon of *Hysteresis*, because it changes perceptibly the shape of the primary current wave, at least for open secondary circuit, making its increase slower, and its decline steeper.

---

[1] In the following, we leave out the circles, which give the instantaneous values of the different quantities, and represent them by their diameters only, as their maximum values.

But, at least as far as my experience goes, even this influence of hysteresis can be accounted for by a simple shifting of the phase of resulting M. M. F., or magnetism, against the phase of impressed M. M. F. by an angle, χ.

By means of this angle χ, or the *ideal* M. M. F. *of hysteresis*, $\overline{O\Gamma_1}$, we derive the *impressed* M. M. F., $\overline{OG}$, and from this the secondary M. M. F., L_1, in the usual way in Fig. 7, the primary M. M. F., $\overline{OL}$.

Only, this angle χ of *hysteretic lag is not* independent of the magnetization, but *decreases* with increasing magnetization; and it seems that the *sine-function* of the angle of hysteretic lag is about proportional to the —.4th power of the intensity of magnetic field:

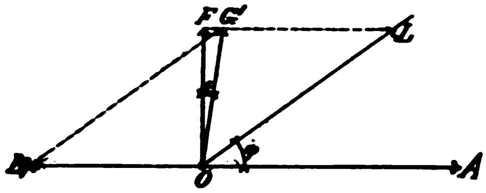

FIG. 6.

$$\sin \chi = a\, B^{-.4}.$$

This angle χ is *independent* of the number of periods, N. For the loss of energy due to hysteresis is *directly proportional* to the number of periods, N, while the loss of energy due to eddy-currents is *proportional to the square* of the number of periods N.

Hysteresis and eddies acting as they do in designing transformers, where we do not yet know exactly how far we succeed in avoiding eddy-currents, we can combine their consideration, and say:

"*Hysteresis in a transformer causes a shifting of the phase of the* RESULTING M. M. F. *and thus of the* MAGNETISM, *against the phase of the* IMPRESSED M. M. F., *that is, the resultant of the primary and the secondary* M. M. F., *by an angle* χ, *which is independent of the number of periods, and only depends upon the kind of iron used, and upon the magnetization. This angle* DECREASES *with* INCREASING *magnetization, and its sine-function is inversely proportional to about the .4th power of the magnetization.*"

"*Eddy-currents cause a shifting of phase of the magnetism against the impressed* M. M. F. *also, by an angle* ε, *which is—below th; saturation limit—almost independent of the magnetization, but depends upon the number of periods so that tan* ε *is proportional thereto.*"

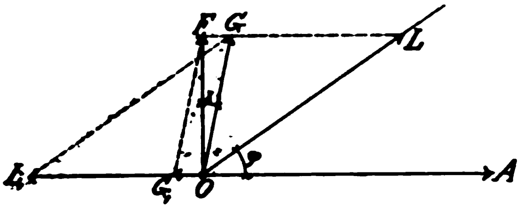

FIG. 7.

In reality this angle ε depends upon the magnetization because of the varying magnetic conductivity of the iron, and decreases for lower and for higher magnetization, reaching a maximum for medium magnetization, at that point where the susceptibility of the iron is greatest. Curves showing the dependence of this angle ε, and the angle χ, upon the magnetization will be shown later on.

"*This angle* ε *of magnetic lag caused by eddy-currents combines with the angle* χ *of hysteretic lag to form an angle,* $\eta = \varepsilon + \chi$, *which, for the usual number of periods, and, if proper care is taken for good insulation of the iron laminæ, can approximately be assumed such that its tangent-function is proportional to the —.3th power of the intensity of magnetization:*

$$\tan \eta = b \times B^{-.3}$$

Let us assume in the transformer treated as an example, that *the angle of true hystertic lag* $\chi = 11.5°$.
" " " *eddy-current lag* $\varepsilon = 7.5°$.
hence " *whole magnetic lag* $\eta = 19°$ (actual test)[2]

That is, the resulting M. M. F., and therefore the magnetism, lags behind the impressed M. M. F., or the combined M. M. F. of primary and secondary current, by an angle of 24°.

In this manner, taking into consideration hysteresis and eddies, we get, in Fig. 8, the complete diagram of our transformers:

Resulting M. M. F. F=2,400 ampere turns. $\overline{OF}$=.72 inch.

M. M. F. *of eddies*: Λ=320 ampere turns. $\overline{O\Lambda}$=.096 inch.

Ideal M. M. F. *of hysteresis*: Γ = 506 ampere turns. $\overline{O\Gamma}$=.152 inch.

Hence, *impressed* M. M. F.: K = 2,538 ampere turns. $\overline{OK}$ = .761 inch; or 138 ampere turns larger than the resulting, or magnetizing, M. M. F. F = 2,400 ampere turns.

These 138 ampere turns I called, when I first drew attention to them, somewhat over a year back,[3] the "*dead turns*," for they are lost for producing magnetism.

Or, if we apply the term "*plant efficiency*," introduced by Kapp for the ratio of the useful E. M. F. to the impressed E. M. F., to the *magnetic* circuit, the "plant efficiency" of this transformer circuit would be,

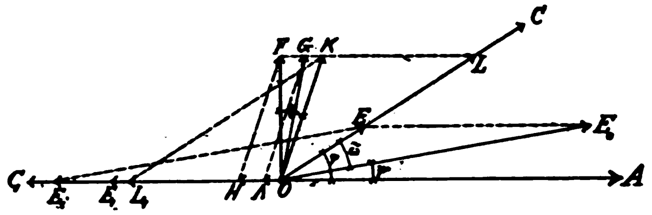

FIG. 8.

$$\frac{F}{K}=\frac{2{,}400}{2{,}538}=.945, \text{ or, } 94.5\%.$$

From the *secondary current*: C_1 = 50 amperes. $\overline{OC_1}$= 1.5 inch. And the *secondary* M. M. F., L_1 = 3,000 ampere turns. $\overline{OL_1}$ =.9 inch.

We get, by means of the parallelogram $\mathrm{O}\,\underline{L_1 K}\,L$, the *primary* M. M. F., L = 4,516 ampere turns. $\overline{OL}$ = 1.355 inch. Hence, the *primary current* C = 56.6 amperes. $\overline{OC}$ = 1.7 inch. Hence, the *resulting, or heating primary* E. M. F. E = 56.6 volts. $\overline{OE}$ =.566 inch.

Now, the *secondary* E. M. F. being, E_1 = 100 volts, $\overline{OE_1}$ = 1.00 inch. This gives the *induced primary* E. M. F., E_1' = 133 volts. $\overline{OE_1'}$ = 1.33 inch, and from this by the parallelogram, $\mathrm{O}\,E_1'\,E\,E_0$, the *impressed primary* E. M. F., E_0 = 183.1 volts. $\overline{OE_0}$ = 1.83 inch.

The *phase of primary current*, angle φ = 32.1°.

The *phase of impressed primary* E. M. F., angle ψ = 9.4°.

The *difference of phase between primary current and impressed* E. M. F., angle $\omega = \varphi - \psi$ = 22.7°.

Further considerations of the highly interesting phenomena of hysteresis I must postpone to a later occasion.

THE BABCOCK & WILCOX BOILER CO. are placing a new 500 h. p. boiler in the power station of the Rochester Railway Co., Rochester, N. Y.

---

[2] Found in a laminated electromagnet, where the loss of energy in the iron was proportional to $B^{1.7}$, given on page 628, June 3.

[3] *Elektrotechnische Zeitschrift*: "Das Transformatorenproblem in elementar-geometrischer Darstellungsweise."

THE WINKLER "UNIVERSAL" DYNAMO.

It is now well recognized that the success of a dynamo in commercial practice depends as much upon its efficiency as a converter of energy as upon the smoothness with which it operates, or, in other words, absence of repairs. In seeking to devise a machine which shall embody all these qualities, Mr. Charles F. Winkler, electrician of the Troy Dynamo Company, of Troy, N. Y., has designed a dynamo which is illustrated in the accompanying engraving, Fig. 1, and which possesses several novel features.

Recognizing the fact that most of the trouble of dynamo machines is experienced at the commutator, Mr. Winkler has designed his machine primarily to make it absolutely non-sparking, and in the second place to make the operation of the machine independent of the load on the outside circuit. For this purpose he has adopted a construction in which the armature is wound with two independent windings, one of which is employed to generate the current taken by the field-magnets and the other to generate current for the external circuit, including the lamps or other devices.

The construction adopted for this purpose in the armature is well illustrated by the accompanying engravings, Figs. 2 and 3, which show respectively a cross-section and a longitudinal view of the armature. As stated above, the field magnets derive their current from a separate winding on the armature. This winding, in order to decrease the air gap as much as possible, consists of straight iron bars c′ c′, the inner ones c being trough-shaped, corresponding to the outlines between the end discs of the armature. The ends of the trough-shaped parts are connected to the adjoining straight bars, the arrangement being the exact equivalent of a Gramme ring winding. The ends where the bars join are connected to a commutator in the usual way. The empty space within the trough-shaped bars is filled up with soft iron wire as shown in Fig. 2, but insulated from the Gramme ring winding. Outside of this winding is placed the winding intended to feed the external circuit, including the lamps. The machine has, of course, two commutators. In the machine illustrated, which is of 400 light capacity, the Gramme ring intended for the exciting armature consists of 40 bars. These are connected to a 40-part commutator and generate 10 amperes at 34 volts with a speed of 850 revolutions. The Siemens winding employed to feed the external circuit consists of 40 coils of No. 3 B. & S. wire, of 2 turns each.

It will be evident that, on account of the separate excitation of the field, the reaction ordinarily experienced between the field and armature and which manifests itself prominently at the commutator by sparking is here absent. As a result, the most violent changes of current in the outside circuit can be effected without showing a spark in the commutator. As the armature alone, with its low self-induction, is in the main circuit, the latter can be ruptured with both terminals in the hands without giving rise to a sensible shock.

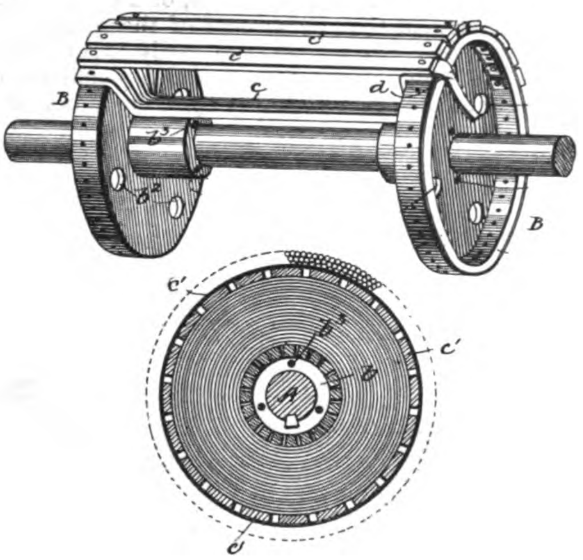
PAT. Nos 412,349 TO 412,353.

The Winkler "Uninersal" Dynamo.

But there is still another advantage gained in this construction, which is due to the fact that it allows of the operation and regulation of the dynamo without a rheostat. By merely shifting the brushes of the exciting current commutator the potential can be varied within wide limits and maintained constant at any point. This allows of a delicate and convenient method of bringing the machine to its correct potential, and overcomes the difficulty of change of potential frequently caused by the heating of wires in the rheostat. It will be evident that the system is also applicable to the construction of arc machines, the regulation of which can be accomplished entirely by the shifting of the brushes, making contact with the exciting current commutator, which, of course, is at very low potential, and which would allow of the main high tension brushes remaining fixed in position. For fluctuating powers, also, this system of regulation, whether for constant potential or constant current, seems well adapted.

The machine above illustrated has been in operation for some time past at the works of Messrs. Miller, Hall & Hartwell, of Troy, N. Y., where it has given most satisfactory service, with practically no attention beyond the necessary lubrication at the bearings. Mr. Winkler has also designed various other sizes of these machines, the manufacture of which will probably be undertaken in the near future.



ARMATURE OF WINKLER'S "UNIVERSAL" DYNAMO.

KERSTEIN'S AUTOMATIC SAFETY DEVICE FOR OVERHEAD CIRCUITS.

THE accidents which are liable to occur and the damage which may be done by the dropping of wires carrying high tension currents upon other wires, such as telegraph, telephone, and light, and *vice versa*, make it desirable to employ some simple device to prevent them. In seeking to overcome the difficulty just mentioned, Mr. Max Kerstein, of the Electric Wire Safety Attachment Co., of Boston, Mass., has recently designed an ingenious circuit-breaker, which acts so that any disturbance in the normal condition of the line at once cuts it out of the circuit and thus renders it harmless. The operation of the attachment will be readily understood by a glance at the accompanying engravings. As shown in Fig. 1, the apparatus consists of two insulating pieces, I I, which are connected by two insulated wires, W W, one end of which is connected to a copper end piece, B, and the other joined to form one terminal of the instrument L¹. Between the insulated wires W W is placed a helical spring, which acts upon a wire carrying a plug, P, which fits into a hole in the copper end-piece B, this wire being connected forming the other terminal of the instrument L, which is connected to the other end of the line. The operation of the instrument will be now readily understood. When the line is in normal condition and taut, the helical spring is under compression, as shown in Fig. 1, the plug P making good contact with the copper end-piece B, the insulated wires W, and out to line at L¹. If the line should slacken but very slightly, or break, the helical spring will be relieved and push the plug out of contact with the end-piece B, as shown in Fig. 2. The circuit will thus be immediaiely broken and the wire beyond the break be rendered perfectly harmless both to property and life. The apparatus, which can be very cheaply constructed, is enclosed in a cover, as shown in Fig. 3, and in practice it is designed to have one attached at each pole so that a break between any pole on a circuit will be followed by immediate rupture of the circuit. It is evident that the device is applicable to electric lighting, and to railway circuits as well; and on the other hand, its attachment to telegraph and telephone circuits will go far towards ending the many complaints which have arisen on account of the dropping of these wires upon the bare electric railway circuits.

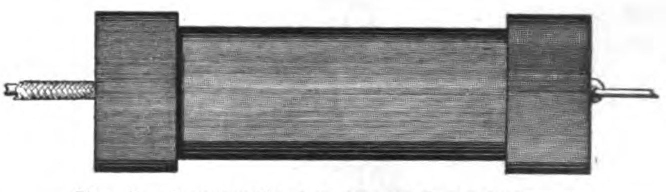

FIG. 3.—KERSTEIN'S AUTOMATIC SAFETY DEVICE.

THE ELECTROLYTIC ASSAY OF COPPER.

IN assaying copper by the electrolytic process it has been observed that sometimes the copper deposited at the beginning of the process is of a dark brown color, and whenever this is the case it usually happens that the remainder of the metal comes down in a "fluffy" condition. There is a short letter on this subject in the *Chemical News* for May 29th, in which the writer who has himself frequently experienced the same trouble states that the cause of it may be traced to using a current that is too strong for the solution. With a weaker current of electricity, and also possibly with a weaker solution of the copper, the metal would be deposited upon the cathode in a firm crust which would possess the usual shiny or rosy appearance. Whether the darkening spoken of above that is sometimes observed at the commencement of the electrolysis is due to the presence of some trace of foreign impurity set free by the current being too strong, or whether the color is due to the molecular state or physical aggregation of the deposited metal, does not transpire.

MR. CHAS. HIGGINS has been appointed Superintendent of Fire Alarm and Police Telegraph, St. Louis. Mr. Higgins has long been connected with the Western Union Telegraph Company, and for a number of years previous to this appointment was Manager of the Merchant's Exchange Office.

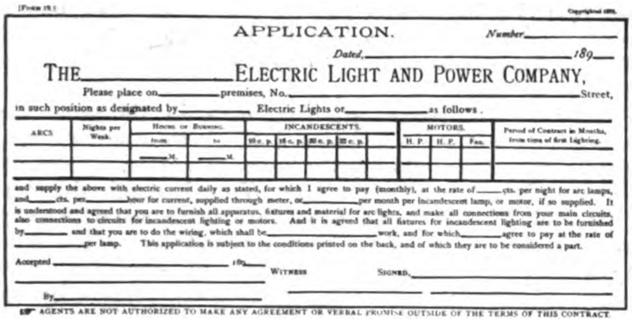
CENTRAL STATION MANAGEMENT AND FINANCE.—VIII.

BY

Horatio A. Foster

Department of Accounts.

In this department the first item is the contract, or, as the writer prefers to call it, the "application," which is, of course, preliminary to all business. Blank No. 19 will be found convenient as furnishing all necessary data and conditions. The usual form of contract is a large document of legal appearance, and is apt to frighten prospective customers off. By presenting this small slip, headed "application," *not* contract, it is found to be much easier to secure its signature. When the application has been accepted by the company an installation order should be issued to the superintendent or other proper authority using the regular Order Blank No. 1. In this connection it is convenient to have a couple of rubber stamps, one for arc and one for incandescents, which will stamp all form of data on the face of the order blank. No. 1 stamp reads as follows :—



[Form 19.] Copyrighted 1891.

APPLICATION. *Number*______

*Dated,*______ *189*__

THE______ELECTRIC LIGHT AND POWER COMPANY,

Please place on______premises, No.______Street,

in such position as designated by______ Electric Lights or______as follows .

ARCS.	Nights per Week.	Hours of Burning.		INCANDESCENTS.					MOTORS.			Period of Contract in Months, from time of first Lighting.

This order, when properly returned with stock and labor list on the back, gives a complete record of the cost of that particular installation, which can be copied into the proper account books, as indicated by portions of the diagrams.

Some larger stations will prefer a special order blank for installation work, and in many cases it is very convenient, as employees often forget items unless they are printed for them in plain sight. Blanks Nos. 20 and 21 have been used largely by the writer for this purpose and are found to be entirely satisfactory. With the Application Blank No. 19, there must also be included another blank, No. 22. which is used for any future increase of the first application, and, being of a different color and filed with the original, it is easily distinguished.

FORM NO. 22.—BLANK FOR INCREASE APPLICATION.

THE CLARK STANDARD CELL.

BY

Elmer G. Willyoung

DURING the past few weeks attention has again been drawn to the subject of standard cells both in the columns of THE ELECTRICAL ENGINEER and elsewhere. The necessity of a standard thoroughly reliable and convenient in use is becoming more and more evident every day. Editorial remarks in the issue of June 3d of THE ELECTRICAL ENGINEER lament the fact that there is still to be made a standard simple in construction and hence available to all. While, of course, greater simplicity is a desideratum in all things, yet we must acknowledge, I think, that there are limits beyond which further simplicity could hardly be expected. I think, too, that THE ENGINEER has hardly used the correct word when it speaks of *simplicity* in the construction of standards. When we consider the form and the methods of attaining standards other than electrical, we see that what is required principally is knowledge how, and practical skill, to construct the standards. The standard yard is *simple* enough, being merely a copy of a certain original which has been securely kept, and yet the exact reproduction of this original standard is a matter which cannot be successfully accomplished by any less a person than one who has given a great deal of attention to this particular order of work as, for instance, Prof. Rogers or Prof. Rowland. The making of the standards of length and capacity sent out by the U. S. bureau of weights and measures, at Washington is, in one sense of the word, a simple matter, all that is required being suitable instruments and *care;* principally the latter.

What has been said of the mechanical standards is equally true of all electrical standards. The making of commercial and laboratory standards of resistance means merely an exact measurement; there is nothing complicated about this operation; the methods suitable for doing it are easy of comprehension; the *one* thing which is required is *care*, and the *greatest* care. The construction of a standard condenser, or of a proper standard of self induction, are *simple* matters and explained quite fully in most text books on electric technics; what cannot be gained, however, except by practical experience is the skill to follow these directions or, to better express the idea, the ability to be careful enough.

If now we will regard standard cells in the same way that we regard other standards, I think we shall see that their construction could hardly be more simple. Take, for instance, a standard Daniell cell. What is required? Pure $CuSO_4$ and $ZnSO_4$ made into solutions of equal density, pure zinc and pure copper, cleanliness and care. The same is true of the various forms of Clark cell—pure materials, cleaniness and care. To expect reliable results by the violation of any of these three conditions would be to expect a violation of the laws of chemical and electrical action.

The greatest bane of a business man is the man who wants something for nothing, and no well-thinking individual can have any real sympathy for such a one. A good standard cell can be had by every one by paying for it either in their own time to make it themselves, or in money, the equivalent of their time, to those who are skilled in the construction of such cells.

To speak more particularly of standard cells. A good many forms have been suggested, as for instance the mercury oxide cell of M. Guoy, the various forms of Daniell, the normal Latimer Clark, as investigated by Lord Rayleigh, and last the modification of the normal Clark, studied by Prof. Carhart. The mercury oxide cell is undesirable on account of its low E. M. F.; it is also not as permanent as the other cells mentioned. The Daniell cell is, undoubtedly, easier to make than the Clark. Slight variations in the ingredients in the former do not affect the E. M. F. as much as similar variations in the latter. Still we must be careful. Our zinc must be pure and unoxidized, our solutions must be of uniform density, and, what is more troublesome than anything else, our copper must be freshly electroplated and free from oxide. Were we to use a standard cell but once in a lifetime or even once in six weeks, all this would be easy to do, but where a cell is to be used every day, or three, or four, or even more, times a day, the care of the cell becomes very laborious. A Daniell cell is *never* ready when you want to use it. Something has always to be done. The copper has to be freshly electroplated, solutions have to be drawn off so as to give the sharp line of demarcation necessary, etc. But worst of all with the Daniell cell is the fact that the cell must practically be *constantly* watched in order to avoid resetting the cell in its entirety every time it is used. If it is not watched and inspected carefully every day, the zinc and copper sulphate solutions will diffuse, and the moment the slightest trace of the copper salt reaches the zinc plate, then farewell to our standard. The E. M. F. immediately drops 2, 3, or 4 per cent. below its normal value, and the cell is useless.

But how is it with the Clark cell? More tedious to make than the Daniell, unquestionably; greater care by far is necessary in using only perfectly pure materials and in preserving them uncontaminated until the cell is filled and sealed. And yet, after all, it is only care that is necessary. By consulting an old note book I find that the first two cells I ever made (according to Lord Rayleigh's directions) when an inexperienced University student agreed in value with one another within eight parts in ten thousand, or less than $\frac{1}{10}$ per cent. This shows that Clark cells *can* be made if one cares to take the pains and the time. The fact, however, that no chemicals, as ordinarily sold by dealers are pure enough for Clark cells, together with the great care necessary in their manufacture, makes it much more desirable and economical for the average busy electrician to purchase his standard of those used to making them, rather than to make his own.

The Clark cell, if well made, is *always* ready for use and *always* reliable; *it does not change its value in time.* To prove this I need but refer to Prof. Carhart's article in the issue of June 3d of The Electrical Engineer, where is printed a comparison of four cells with one another, two of the cells having been made four years before the other two. Further, one of these older cells had been used indiscriminately by all electrical students frequenting the laboratory during these four years without any regard whatever to electrical proprieties; nevertheless, as is seen, these cells agree with one another within $\frac{2}{100}$ per cent. and the old ones with the new ones within the same percentage.

Thus we see that the Clark cell possesses two of the principal requirements of a good standard. Another qualification possessed by it, and by no means common to all standards, is durability or, to use other phraseology, lack of excessive delicacy. To use it and secure thoroughly reliable results only a few simple precautions need be observed. It should always be used with a resistance in circuit, and the circuit of the cell kept closed no longer than strictly necessary. Should, however, the circuit be closed on so low a resistance as 10,000 ohms for as long as two or three minutes no particular harm will result. The polarization thus produced will not affect the E. M. F. by more than about $\frac{1}{10}$ per cent., and the cell rapidly recovers this small amount when left on an open circuit. The Clark cell also may be very conveniently carried about the laboratory. This is not the case with the Daniell, which needs to be handled with great care to prevent diffusion of the solutions or spilling. Being small and capable of being very conveniently mounted, the Clark cell is a much handier thing to use than any other form of standard known.

It has always been supposed that the Clark cell was a very frail thing to handle and that, at best, it could not be depended upon for longer than a very brief period. Many people have unpleasant recollections of Clark cells imported from abroad, and found nowhere near standard when they reached this side, if indeed they appeared to possess any E. M. F. whatever. I have a letter from one of the most prominent electrical authorities in this country before me as I write, dated about one year ago, in which he says, "No Clark cell can be made which will stand transportation." Nevertheless such a cell has been made and is being transported with perfect success continually. Tests made upon cells of Prof. Carhart's form, which have been shipped from Ann Arbor to Philadelphia and back again, show results agreeing with one another within $\frac{3}{100}$ or $\frac{4}{100}$ of one per cent. A short time ago in order to see how much jarring and shaking a cell would stand I took one up and shook it vigorously, just as one would shake a bottle of medicine, to thoroughly mix the contents; after eight or ten seconds' shaking of this kind I allowed the cell to rest about five minutes and then repeated the shaking. A measurement was then taken with the result below:

Before 1st shaking: Resistance to balance . . 9,134 ohms
After 2d " " " " . . 9,129 "

or a difference of about $\frac{4}{100}$ per cent. This shaking was so vigorous that considerable of the mercury got broken up and mixed in with the salt.

In the orthodox Clark cell a good deal of trouble has been experienced in the sealing, which would often crack away from the sides of the tube in which the cell was mounted, thus allowing the solutions to evaporate. By the use of a special compound, having nearly the same coefficient of expansion as glass, the seal as made in Prof. Carhart's cell is much more effective than in the usual form. Should, however, slight leaks develop, it has been found that the E. M. F. is not appreciably changed thereby.

That the Clark cell has proved its superiority over the Daniell is shown by the fact that the Electrical Standards Committee of the English Board of Trade are considering its use as the official standard, and they have drawn up a provisional memorandum of instructions for making these cells.

In conclusion, it may be said that the Clark cell as a standard of E. M. F. is probably as easy to make, if not more so, than any other standard known of any kind; and in the hands of a man having need of standards, and hence capable of using them, will probably give less trouble than any other standard or standard instrument. Always ready for use, an important measurement can be completed with it before a Daniell could be given half the necessary inspection. No laboratory is complete without a Clark cell.

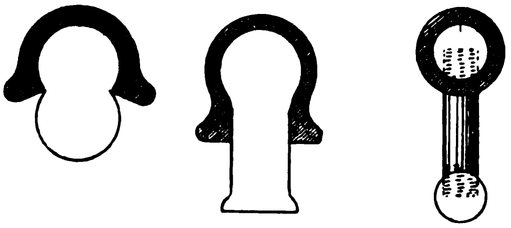
A COMBINED FEEDER AND TROLLEY WIRE.

BY

Birdsall.

The recent published account of an insulated trolley wire called to mind some sketches of a combined feeder and trolley wire made by the writer nearly a year ago.

In the accompanying sketches, which are copied from my note and sketch book, the shaded portions represent the insulation, the unshaded portions copper.



Figs. 1, 2 and 3.—Birdsall's Combined Feeder and Trolley Wire.

The writer has long advocated the use of a trolley wire the shape of Fig. 1, as by this form all flashing due to the trolley wheel striking the clips would be eliminated.

Having arrived at a wire of this section, it naturally follows that the upper half could be insulated, thus serving as a guard wire.

AN EFFECT OF HIGH PERIPHERAL VELOCITY.

A Montreal correspondent of *Nature* communicates the following result of an experiment regarding the whirling of steel bands, about which there has recently been some controversy in that journal:—A weldless steel flash, with spherical body 12 in. in diameter and $\frac{3}{8}$ in. thick, constructed for use in a centrifugal milk separator, to revolve about its axis of symmetry at a normal speed of 7,000 revolutions per minute, was whirled at a gradually increasing speed, with a view to ascertaining the "bursting" velocity. At 16,000 revolutions per minute the body of the flash had bulged 2 in. in diameter. This is equivalent to an extension of 17 per cent., the peripheral speed being 840 ft. per second (about 570 miles an hour), and the tension 31·5 tons per square inch.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers*

VOL. XI. NEW YORK, JUNE 24, 1891. NO. 164.

The very discovery of law is regulated by law.—Josiah Parsons Cooke.

THE ART OF INSULATION.

IN keeping with the advances which have been made in other departments of electricity in its practical applications, changes are gradually taking place in the current ideas regarding insulation, and new methods are being applied in conformity therewith. The limited supply of gutta-percha and rubber has for some time past made it apparent that unless new sources of supply open up, insulating materials other than those mentioned must be looked for to meet the enormous demand for insulated wire of various descriptions. And again our preconceived notions of the insulating properties of air have been somewhat modified of late by demonstrations carried out with high-tension currents, which leave no doubt of the fact that air, except under very special conditions, cannot be employed as the insulating medium for very high-tension currents. Up to the present, of course, solid insulators are almost of universal application, and will probably continue to be the only practical method for a long time to come; but the resisting qualities of oil have been proved to be so remarkable that for many purposes it cannot fail to find very many applications in the future, especially in connection with high-tension transformer work, both in the station and in the distributing system.

But in addition to the development of methods for obtaining electrical resisting properties in insulators, there are distinct signs of improvements in other directions, more particularly where the capacity enters as an important factor. Thus, it is scarcely three years ago that the standard specification for telephone cables adopted by many telephone companies in this country limited the static capacity of the conductor to .18 microfarad per mile, which at that time was considered as low a capacity as could be produced commercially and still retain the other necessary properties of the conductor. But astonishing as it may seem, the recent improvements in cable manufacture have lead to the gradual lowering of the capacity until at the present time manufacturers guarantee cables to have less than one-half the capacity specified three years ago. This condition has been brought about largely by the adoption of paper as an insulation.

The facts just pointed out are but a few of the many which we think go to prove that the misgivings of those who hold that the art of insulation has been lagging behind the progress in other electrical branches are unfounded. Not, indeed, that improvements are not still wanting, but if the rate of progress manifested in the last five years is maintained, there need be no fear of lack of means of confining the current within channels both safe and suitable for the various classes of conductors.

DEATHS FROM ELECTRICITY IN NEW YORK.

THE usual yearly returns of the number of deaths in this city due to accidents, and of the nature of the accidents, have now been made public. Dr. R. S. Tracey's report for the Health Board shows that 1,333 deaths in this city during 1890 were due to accidents and negligence. To the electrical engineer, these figures, after the attack that has been made on electricity as a means of distributing light and power, would be rather amusing, but for their intrinsic sadness in showing how great is the waste of human life in our great cities. Columns upon columns fill the papers about the perils of the deadly current—even the poor innocent trolley that never took a single life is also called "deadly"—and yet when we look over these returns we find that electricity is held responsible for *just two deaths!* Neither of them was a necessary sacrifice, but may fairly be attributed in large measure to the neglect of even ordinary precautions by the victims. Only two out of 1,333. It would be extremely interesting to have the statistics of newspaper columns of gush and drivel and sensation per death; probably, those two deaths took up as much space that was not valuable as nearly the whole 1331 remaining. There are 116 deaths ascribed to suffocation. Has anybody seen an article on that subject? There are 11 due to the careless use of kerosene; 62 to sunstroke. Has anybody seen any remonstrance about the need of insulated sidewalks for summer time? There are 71 deaths attributed to railways, and 44 to street vehicles; but poor James Redpath, once a prince of New York journalists, run over in the street, could go down to his death with hardly a protest from his old colleagues and without any suggestion that all the cars should stop running until every inch of track had been put in order. No fewer than 36 deaths were caused by falling down elevator shafts, and 42 are written up to the account of poison, chiefly illuminating gas; but Mayor Grant has not indulged in heroics about elevators, nor has he been heard to say that it was a peculiar part of his duty to keep the citizens from dying from the inhalation of illuminating gas.

That there are only two deaths due to electricity is something which the Board of Electrical Control may reasonably take pride in, for the freedom from accident is the result of good rules intelligently lived up to by the local companies. Dr. Wheeler has had an ordeal as expert of the Board that few men would care to go through, but these figures stand to his credit as evidence of care and ability that nothing can gainsay. Accidents will happen with any of the great forces that modern civilization uses, but it is a public duty to keep the number down to the minimum. We make bold to say that the returns of 1890 show an electrical minimum which we can all point to as an overwhelming proof of the safety of electricity, for never was there so much high tension current used in this city before.

THE LIGHTNING ROD QUESTION.

In our last issue we drew attention in these columns to the fact that some diversity of opinion still existed as to the true functions of the lightning rod, and hence it is not a matter of surprise that the mind of the layman should be clouded with uncertainty. The paper read before the American Institute of Electrical Engineers by Mr. N. D. C. Hodges has served again to call attention to this subject, and in response to queries from the New York *Tribune* concerning the necessity for lightning protection, the nature of electrical discharge, and the manner in which the rod should be erected, Prof. Elihu Thomson has given his opinion, which is evidently the outcome of much thought.

Prof. Thomson thinks there can be no question that a properly constructed and arranged lightning rod will afford complete protection of buildings from the effects of lightning discharges. In his opinion, a lightning rod does not have any considerable effect in conducting off discharges from the cloud silently, for the reason that the development of the conditions of the discharge from cloud to earth is frequently too sudden to allow any rod or rods to effect this work of conduction in a silent manner. He admits that on this reasoning the presence of a lightning rod may, and perhaps often does, conduce to the building being struck by lightning, but it is much better, evidently, to have the building struck a number of times without doing any harm than run the risk of having it once struck without any means of conduction, except through the poorly conducting portions of the building, which are almost sure to suffer injury or destruction. Prof. Thomson is of the opinion also that lightning rods are not of much utility in the case of buildings which have metal pipes running from the ground up to the highest story and through the roof, especially if these pipes should extend to a considerable height above the highest part of the building; and that lightning rods are but of little use for buildings adjoining tall chimneys or church spires, themselves provided with good lightning conductors. From these conditions Prof. Thomson points out that the most perfect lightning protection is obtained when the building is virtually in a metallic cage, the parts of which in connection with the earth are very thoroughly grounded, but such thoroughness as this is not necessary, as even with a large building the carrying of a conductor down each corner and grounding it would be sufficient.

As regards the size of conductors and their form, Prof. Thomson draws attention to the fact that a half inch iron rod has never been known to be injured by the passage of the lightning discharge, and he says that a one inch iron pipe with screw joints and thoroughly painted or a flat strip of copper, $\frac{1}{16}$th inch thick by 1½ inches wide, securely tacked to the building would answer all purposes. With regard to the query "What is the Nature of the Electrical Discharge?" Prof. Thomson sums it up briefly by stating that it is the conversion of the electrical energy into the energy of light and heat. According to Prof. Thomson, a discharge of a cloud to earth in a lightning flash is simply the sudden relief of electrical pressure due to a condensation or accumulation of electricity induced by the formation of rain drops. An accumulation of electricity in a clould seems to be concomitant with a sudden condensation of vapor, which takes place on the cooling or rarefaction of the vast bodies of moist air. If the air before the condensation was in any way electrified, however slightly, the condensation or conversion of the cloud into drops of water would be very apt to be followed by the existence of an electrical charge in the cloud. A thunder storm ceases when the condensing action stops. Concerning the action of a lightning rod in saving a building from harm, it is merely a provision of a path or centre of action for the discharge in the vicinity of the building, of such a character that the discharge selects it in preference to forming a centre of discharge or path for itself through the building. On account of the high potential of the lighting discharge, it is evidently without avail to insulate rods from buildings, and it matters very little whether they are insulated or not. Where there are large masses of metal in a building it is well to connect them to the ground as well as to the lightning rods.

As regards the type of dissipatible conductor and the ideas advanced in its favor by Mr. N. D. C. Hodges, Prof. Thomson believes the latter not to be grounded on correct principles. As lightning does damage only when it avoids the lightning conductor and passes through the building, Prof. Thomson argues that if it should avoid Mr. Hodges' type of dissipatible conductor, it would do equal damage. The fallacy, according to Prof. Thomson, consists in the fact that Mr. Hodges supposes the work of the discharges to be confined to that very short length between the top of the building and the ground; but, according to Prof. Thomson, the giving out of energy of a lightning discharge is by no means confined to the building which is struck or the lightning rod which carries it, but, on the contrary, this portion of the path receives but a small fraction of the total energy. Again, to provide a lightning rod which is partly or wholly destroyed during a thunder storm would invite danger from a second discharge, one against which no provision could be made. In conclusion, Prof. Thomson is of the opinion that Franklin's great invention of the lightning rod has been brought into discredit principally by the poor methods adopted in the erection of such rods and for which the lightning rod man is largely responsible. With the proper means of construction, therefore, the simple, efficient lightning rod provided by Benjamin Franklin, with the improvements in details and disposition about the building, is quite able to afford the right kind of lightning protection for buildings.

EXPERIMENTS ON THE ELECTRIC DISCHARGE IN VACUUM TUBES.

BY

Elihu Thomson

I HAVE been much interested in the account of novel phenomena given under the title "Some Experiments on the Electric Discharge in Vacuum Tubes," by Prof. J. J. Thomson, and published in your issue of June 10, inasmuch as several months ago I tried the same, or a very similar, experiment to that in which an induced discharge in a closed circuit vacuum receiver was obtained.

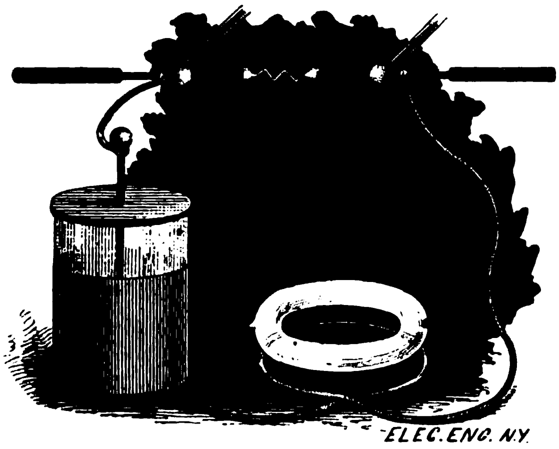

FIG. 1.—ELECTRIC DISCHARGE IN VACUUM TUBE.

Briefly, my experiment was performed with a closed ring made of a glass tube about one inch in diameter, the external diameter of the ring being about six inches. This was exhausted to a fairly good vacuum and laid alongside of a single turn of heavily insulated wire, which formed part of the discharge path from the outside of a Leyden jar, arranged to be charged and discharged rapidly by a Toepler-Holtz machine. It was found that at every discharge of the jar there was a discharge in the tube giving a band of light in the vacuous space. The accompanying engraving Fig. 1 shows the arrangement of apparatus as just described.

It will be evident that to obtain the greatest value of electromotive force in the discharge tube the inducing turns should not exceed one, as otherwise the arrangement becomes a transformer, reducing the potential in the discharge tube. The wire used for the single inducing turn should be very heavily insulated and its turns separated, or the discharge may break through and, instead of going around the turn, short-circuit it. The potential induced in a single turn under these conditions of the experiment may easily reach 10,000 volts or more.

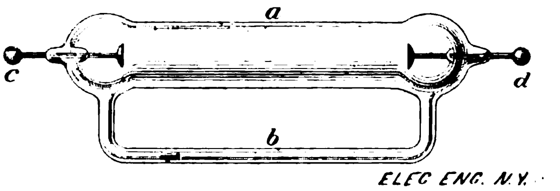

FIG. 2.—ELECTRIC DISCHARGE IN BRANCHED VACUUM TUBE.

Curiously enough, the experiment of Prof. J. J. Thomson, in which a small pellet of mercury in an exhausted tube stopped the discharge, had its counterpart in my own experiments, as follows: I had constructed a two-way discharge tube, Fig. 2. One branch, *a*, was large in diameter and the branch *b* was of barometer-tube section. Wires sealed at *c*, *d* enabled a discharge to be passed. A small globule of mercury was placed in the tube and could be shaken down into the barometer tube and out into the large tube at will. Though the discharge would not always divide and pass through both tubes from *c* to *d*, it sometimes did; but the interposition of the mercury globule in the small tube stopped the discharge through it. Even without the mercury the discharge would often fail to pass, but reversing the coils of the Ruhmkorff coil used would often cause its derivation.

In one case, even when the mercury was in the small tube, the discharge passed, but the approach of metal objects near the tube would stop it temporarily; on their removal the discharge was resumed. This condition was so critical that it could not again be obtained, though efforts were made to obtain it. I have thought it well to record these observations, made independently, especially as the conditions were somewhat modified.

A THERMO-ELECTRIC METHOD OF STUDYING CYLINDER CONDENSATION IN STEAM ENGINE CYLINDERS.[1]

BY PROF. EDWIN H. HALL.

THE subject of cylinder condensation is one that has always been prominent in the study of the steam engine. It is considered that in some engines as much as 25 per cent. of all the steam that enters the cylinder goes through the cylinder as water—that is, during the forward part of the stroke. Writers upon steam engineering have devoted a good deal of attention to the discussion of the cause of cylinder condensation, with perhaps less attention to suggestions for remedy. The cause of cylinder condensation is this, that when the cylinder is thrown into communication with the condenser, rapid evaporation takes place of the water remaining on the wall, and that rapid evaporation under the diminished pressure cools greatly the cylinder wall.

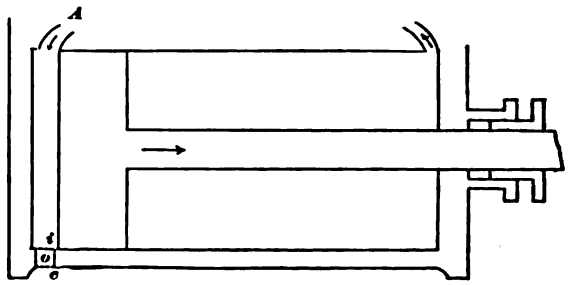

FIG. 1.

I know that steam engineers are by no means in agreement as to what caused the cylinder condensation, some believing that the steam coming in here at A, Fig. 1, was cooled by contact with a layer of water remaining over from the previous stroke—the layer of water upon the inside of the cylinder. Knowing the pressure at this part of the stroke, *c*, Fig. 2, and the volume occupied by the steam, we can tell what weight of steam there is in the cylinder as *steam*. It is found frequently that there is more steam in the cylinder at the end of the stroke than at the beginning of the expansion. According to Mr. Dickerson, in a paper read before the Electric Club, of New York, this was due to the leakage by the valves by which steam was admitted, when the pressure in the cylinder fell low. It seemed to me that we might test the question how much heat enters the cylinder wall by a thermo-electric method. Let *e i*, Fig. 1, represent the thickness of the cylinder wall; *o*, is a hole about ¾ of an inch in diameter; the thickness of the wall is about ¾ of an inch. Screwed into the hole is a plug, Fig. 3, having at the end a slice of iron, *s*, of known thickness.

It being my purpose to find what the temperature was at a particular depth in the iron at a certain point of the stroke, I wished to have that temperature as exactly as possible what it would be if the iron were in a normal condition—that is, if this were in a solid cylinder instead of being in a prepared plug. To get that I found it necessary to have a heat conductivity which was more nearly like that of iron than the heat conductivity of antimony and bismuth, which were first tried. Nickel and iron make a very good thermo-electric pair. Fig. 3 is a plug with a hole bored completely through it. There is a slice of cast iron, S, ground to a particular thickness, which is screwed on at the end of the plug, making a steam-tight joint.[2]

---

[1] Abstract of a paper read at the General Meeting of the American Institute of Electrical Engineers, New York, May 20, 1891.

Into this hole is put a core of nickel insulated from the iron except where it strikes the slice. The nickel is soldered to the iron.

The distance from the outer end of the core to the farther surface of the slice was measured carefully before soldering, and after soldering. In no case did these measurements show the thickness of the solder to be as much as .02 mm.

We know very definitely, then, the depth at which the contact takes place. By experiment, I found that the heat conductivity of nickel is perhaps 15 or 20 per cent. less than that of cast iron,[3] but still nearer the heat conductivity of cast iron than any other metal that I could get that would make, with iron, a good thermo-electric junction. The specific heat of nickel is near that of iron, which again is as important, perhaps, as the matter of the thermal conductivity. Now from the nickel core I lead a nickel wire, both being made from the same bar of which I had determined the conductivity; and from the iron an iron wire. This and the one of nickel were slender bars, about 15 cm. long. These junctions *i* and *n*, Fig. 3, are put in a pot of paraffine, and I go through the processes which I have indicated already, and connected to a galvanometer. The paraffine is then heated, and when the temperature of the two junctions *i* and *n* are the same as those in the plug I N the current will cease. But a current is manifested when the respective junctions are at different temperatures. In my latest experiments the fly-wheel made about 60 revolutions per minute, and contact lasted about $\frac{1}{60}$ part of a revolution. A cam pushes two pieces of brass together without touching either of them directly.

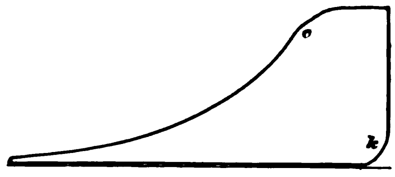

FIG. 2.

I had three plugs like this made. With one the slice of iron was half a millimetre thick (.051 cm.); with the other, a millimetre thick (0.101 cm.); with the other, two millimetres thick (0.203 cm.) Let Fig. 2 be the indicator card from the engine with which we are making this test. I used first the plug with the thinnest slice, and found the temperature at half a millimetre at that part of the stroke, K, Fig. 2, just before steam is admitted. I did the same with the millimetre slice and with the two-millimetre slice. Let the line D, Fig. 4, represent 4 mm. of the thickness of the cylinder wall, points at depths of ½, 1, and 2 mm. being marked upon it. Suppose that distances to the left from the line D represent excesses above 109 degrees (109 degrees centigrade being the temperature of the outer surface of the cylinder wall). With the half millimetre slice at the part of the stroke, *k*, I found an excess above 109 degrees of 8 or 9 which I will represent by the distance *a*. With the millimeter slice I find the temperature to be greater at this part of the stroke, and the excess above 109° being represented by the distance *b*. With the two-millimetre slice the temperature was not very different from what it was with the one millimeter. Through the tops of the lines *a*, *b*, and *c* I draw a curve.

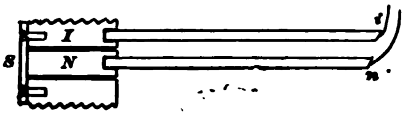

FIG. 3.

I make similar determinations for that part of the stroke *c*, Fig. 2. I find the temperature at half a millimetre depth has risen to 131 degrees more or less. The temperature at a depth of a millimetre is a little higher. This point, ½ mm. deep, has already begun to cool. The fact is that in my engine the cut-off is, like Fig. 2, pretty gradual, so that re-evaporation very likely begins before cut-off is complete. I suspect, however, that 131° is too low for the temperature at a depth of ½ mm. At the depth of two millimetres the temperature is not as high as it is at a depth of 1 mm. At a depth of two millimetres in the iron there is, however, a jump of some 4 or 5 degrees centigrade.

The inner curve, Fig. 4, represents the condition of things at the part of the stroke *k*. The other curve represents the condition of things at that part of the stroke *c*. The curves are by no means accurate, and they are very incomplete; but supposing them made perfect, I have merely to put on a planimeter to measure the area between those two curves, and it is then easy to determine how much the heat in the cylinder at the part *c* of the stroke exceeds the heat in the cylinder at that part *k* of the stroke, and this excess of heat is the heat which has been given up by the steam to the cylinder-wall, which has been done during the admission. Allowance should be made, of course, for the loss through the wall meanwhile. Then I compare that with the indicator card and see whether the two are in agreement.

I have made some tests for points at other parts of the stroke. I found that at a half millimetre depth the temperature at cut-off has already passed the maximum, that it falls rapidly during expansion, and at the part of the stroke near release it is only a few degrees higher than at the end of the exhaust. But the parts deeper in the cylinder are, of course, slow to cool. In fact, the heat rushes into the wall during admission; then, as soon as the pressure is relieved, the water begins to evaporate from the inner wall and the heat ebbs back, and is spent, some part of it, in forming steam during the expansion, but not all of it; a considerable part remains at the end of the stroke, to be spent in evaporating water, which is still clinging to the wall of the cylinder. As I have said, this research is by no means complete, but it has gone far enough to indicate that a very large quantity of heat goes into the cylinder wall. A very rough calculation from my experiments indicates that in the engine I am using,[4] according to the best estimate I can make, probably two-thirds as much steam is condensed upon the cylinder wall as remains active at the beginning of expansion. I should say that one-third probably of all the steam that enters the cylinder is condensed upon the cylinder wall upon the first quarter of the stroke. How much of that is re-evaporated during the stroke, and so helps, more or less, I not yet know. According to the indicator cards taken during the experiments with the plugs the weight of steam in the cylinder at the end of expansion is about 1.25 times as great as just after cut-off. How much heat is absorbed by the layer of water which remains over from the previous stroke I cannot tell. I think there is some evidence that a layer of water does remain over from the previous stroke. This examination shows, however, that the iron is exceedingly effective in cylinder condensation, and it suggests

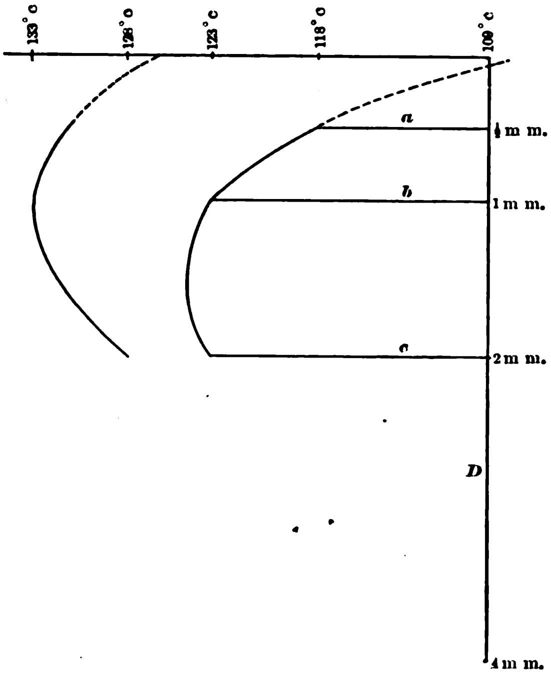

FIG. 4.

---

[2] In some of the experiments this joint was not perfectly tight, for *water* was sometimes seen to come out by the *core* N before the plug became hot. Generally upon such occasions the leaking appeared to cease when the plug became hot. The fact probably is that the joint continued to leak slightly, but leaked *dry* steam, the temperature at the outer end of the plug being about 109° C., and at the inner end considerably higher. Both experiment and reason indicate that the effect of such leakage upon the temperature found was slight.

[3] The nickel used was of fair commercial quality. I am not yet prepared to publish details of the measurement of its conductivity.

[4] The engine is a Kendall & Roberts, 10 inch cylinder with 15-inch stroke. This maximum pressure is about 33 pounds (above atmospheric) with an expansion of about 4—not quite that (about 3¾)—and about 60 strokes to the minute.

the question whether it is not possible to coat the inner wall of the engine or the cylinder heads with something which would prevent, to a considerable extent, this condensation.

The research of which I have here given an account has been carried on with money from the Rumford Fund of the American Academy of Arts and Sciences. For indispensable assistance in the investigation I am indebted to Messrs. Barron, Curtis, Hale, Kendrick, and Page, members of a class at Harvard College engaged in a study of the steam engine.

THE EDISON KINETOGRAPH.

In addition to the account already published in The Electrical Engineer of the Edison Kinetograph, which is attracting such widespread public, as well as scientific, interest, we are glad to give our readers the following description, taken from the excellent article of Mr. George Parsons Lathrop in *Harper's Weekly*. After giving a résumé of previous achievements in instantaneous photography and the events which led to Mr. Edison's invention, Mr. Lathrop continues:

"The kinetograph reproducer now in use at Edison's laboratory (Llewellyn Park, Orange, New Jersey) is regarded only as the basis for still further development. Photographs are taken first from a living person in active motion. This is done with a camera regulated by electricity, having a mechanism and other details of preparation specially devised for the purpose.

"The photographic impressions are received through it upon a thin gelatine band which runs along with prodigious rapidity behind the lens. Taking 46 pictures in a second, it would take in one minute 2,760, and in one hour 165,600 of them. With the pictures an inch wide and spaces of an inch between, it must travel 7⅔ feet in every second. But since the strip is at rest during nine-tenths of the second, the passing of these 7⅔ feet is really all done in *one-tenth* of a second. That is, the strip, when it does move, goes at the rate of about 50 miles an hour. It receives a perfect photograph of the moving figure in a small fraction of a second. The shutter closes and opens like a flash, and the gelatine band receives on another spot another perfect picture. A point of the utmost importance is this: *only one forty-sixth of a second* can be allowed for the whole process of taking a photograph *and for also moving the band along a certain distance*, so that it will be ready for the next impression. It is essential to expose the band to the light for the longest possible part of this fraction of the second. To give it such exposure as to obtain a distinct image, yet carry it forward quickly enough to receive another and another, up to the number of forty-six, was perhaps the greatest difficulty which the inventor had to overcome.

"The main features of the reproducing mechanism are not difficult to describe. Fig. 1 shows the simple device for unreeling the photographed film from one coil, marked A, and carrying it up over the wheel B, past the aperture in the shutter and box at E. As it runs on beyond that point it is caught by numerous little teeth on the wheel to the left, *i.e.*, C, controlling the motion of the strip, and giving it an exact uniform progress. Finally, the strip is carried downward and coiled again for future use on the reel designated by D. The compartment L contains the illuminating bulb, fed by wires from below, and a small electric motor, specially made for this machine, supplies the needed power. In Fig. 2 the arrangement of the strip and of the shutter between it and the glass opening is outlined more in detail. The shutter is circular, and in both diagrams is lettered S S. Fig. 2 represents it as though we were looking down upon it vertically, with the gelatine strip B B lying flat under it.

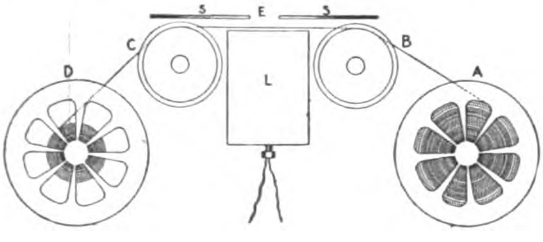

Fig. 1.—The Edison Kinetograph.

"Now in the circular shutter there are four openings 1, 2, 3, 4, and it is so completely connected with the strip-moving mechanism as to act in perfect unison with it; so that when the shutter revolves these openings one after another are brought opposite to and over one of the small pictures on the strip. As that picture glides on away from the aperture the solid part of the shutter in the same fraction of a second intervenes between us and that blank space on the strip which separates every picture from the next. So through the shutter openings we behold only the flying photographs, and none of the blank portion of the gelatine strip or ribbon. It is in this way that we receive a continuous pictorial impression; and as each photograph slightly varies from the rest, they impart to our continuous impression a convincing illusion of life-like movements. The usual and most effective manner of using the kinetograph will be to project the figures from this lens, greatly enlarged, upon a screen, where they may be shown, if need be, as of life-size.

"It should be borne in mind that each time the gelatine band is arrested so as to receive an impression through the camera lens it must 'stop dead.' It cannot be allowed to vibrate or move, for if it stirs at all the photograph will be shaky or blurred, and its usefulness for enlargement be destroyed. The little picture when thrown up to life size is magnified 57,000 times; therefore to have any value when so greatly enlarged it must of course be perfectly clear and accurate. This compels the use of very sharp lenses; and the gelatine band must also be peculiarly sensitive in order to register the impression quickly yet sharply.

"There is a different sort of kinetograph recorder which has not yet been shown, even experimentally, in which the recorder contains a revolving cylinder like that of the phonograph. Only, instead of wax, it will be made of highly sensitized glass; and upon it, while it turns, there will be taken a series of photographs one twenty-thousandth of an inch square each—*i.e.*, invisible to the naked eye except as very small dark spots. These will impress themselves on the glass cylinder in a continuous spiral line, like that of indentations upon the phonograph's wax. The cylinder will have a reproducing attachment corresponding to the phonograph reproducer, but, in this case, consisting of a microscope. So while the cylinder turns upon its axis one may gaze through the microscope and have the whole action which has been imprinted on the spiral series of microphotographs unrolled before him, the figures in motion and enlarged to cover the field of the microscope."

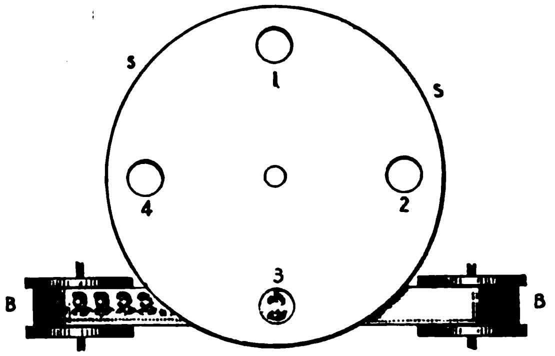

Fig. 2.—The Edison Kinetograph.

Society and Club Notes.

FIRST SMOKING CONCERT AT THE ELECTRIC CLUB.

The entertainment given at the club on Thursday night last, though somewhat in the nature of an experiment, proved very successful, and the first smoking concert bids fair to lead on to a number of enjoyable evenings of the same nature. The concert was given in the parlors of the club, a small platform being built at the street end, while down through the rooms were a series of tables equipped with "churchwardens" and shag tobacco. The Messrs. Steinway generously favored the club with the loan of a fine grand piano. The programme was opened with a piano solo from Massenet's "Le Cid," by Mr. G. M. Phelps, who was followed by Mr. C. McL. Paine, in the "The Daily Question." This song brought as an encore a beautiful new song by Mr. George H. Guy, "Love Comes Nevermore," fitted to words by the late Philip Bourke Marston. Mr. R. Varley then gave, on the violin, a "Romanza" by Carl Bohn, and one of Moszkowski's "Spanish Dances." Mr. M. J. Sullivan gave a musical recitation "On the Banks of the Rappahannock," an incident of the Civil War. Mr. Guy next aroused great enthusiasm by his "Magyar Dance," dedicated by special permission to Mrs. Kendal, and now played for the first time in public, by himself. The members showed themselves very appreciative of the compliment and of the very pretty dance itself. An aria from Bach followed, by Dr. Leonard Waldo, violincello, Master Waldo, violin and Mr. Phelps, piano. The first part closed with a clever phonograph recital by Messrs. M. C. and M. J. Sullivan. After a brief interval, Master Waldo sang with much taste, Robaudi's "Bright Star of Love," with 'cello obligato, by his father. Then came Mr. Paine whose well trained tenor voice did justice to another new and taking song by Mr. Guy, entitled "Exiled." Mr. Varley gave Raff's "Cavatina" on the violin, and Mr. R. F. Outcault with the help of Dr. Wangemann at the piano and of his own banjo, brought down the house with his electro-topical song, "In Other Respects We Are Doing Quite Well." Mr. F. R. Colvin then gave some waltz music, and the phonograph closed the proceedings, which filled nearly three very happy and pleasant hours.

THE TELEGRAPHERS' BROTHERHOOD AND THE RAILWAY TELEGRAPHERS.

A SPECIAL dispatch from St. Louis, of June 18th, says: "It is practically settled that the Telegraphers' Brotherhood and the Order of Railway Telegraphers will amalgamate, and that one order will be taken into the Federation of Railway Employees. There has been very strong opposition to this, and this opposition at one time went so far as to threaten injunction proceedings. A secret conference was held last night, and the clause prohibiting strikes was eliminated from the constitution in order that the order might go into the Railway Federation. A majority of the delegates to the Railway Telegraphers Convention were in favor of joining the Railway Federation, but many did not want to amalgamate with the Brotherhood.

"This morning telegrams were received from both F. B. Sargent, Chief of the Brotherhood of Firemen and President of the Supreme Council of the Railway Federation, and from George Howard, Chief of the Conductors' Brotherhood, stating that neither the order nor the Brotherhood would be received into the Federation as separate bodies. "Unite and then come in" was the purport of the messages. This was the situation when the convention met to-day. The sessions are secret, but it can be definitely stated that the proposition to change the constitution was adopted by a vote of 115 to 12. Then a committee was appointed to confer with a committee of the Brotherhood" The conference failed of its object, however, and the two bodies still remain apart, though friendly.

ANNUAL MEETING OF THE RAILWAY TELEGRAPH SUPERINTENDENTS.

The Association of Railway Telegraph Superintendents held its tenth annual meeting at Cincinnati, O., on June 17, President G. T. Williams in the chair. Thirty-six members were present and twenty-one new members were elected. Mr. Chas. S. Johes, of the Illinois Central, was elected president, L. H. Korty of the Union Pacific, vice-president; P. W. Drew, was re-elected secretary and treasurer. The association was invited to hold its next annual meeting at Denver, and voted to do so on June 15, 1892. Mr. E. St. John, general manager of the Chicago, Rock Island and Pacific Railway, promised free transportation both ways to members and ladies. Messrs A. R. Lingafield, C. G. Sholes, and F. M. Duncan were appointed a committee of arrangements for that meeting.

The annual dues were raised from $3 to $5, after the current year.

Mr. G. H. Lang read a paper on the "Care and Maintenance of Electric Block Signals," after which Mr. W. B. Leonard spoke highly of the results obtained with the phonoplex. Mr. U. J. Fry then read a paper on the quadruplex, bringing out various ways of utilizing it in railway service. Mr. C. Selden, in the discussion, told of his experience in 1869 at Cincinnati, when, with Mr. E. T. Gilliland, he was applied to by Dr. Nicholson for a polarized relay. The claims of Dr. Nicholson were afterwards recognized by the Western Union Co., and he received compensation from the company for his quadruplex.

Exhibits were made during the meeting by the Hall Signal Co.; the Gill-Alexander Electric Manufacturing Co.; the Electric Secret Service Co., of New York, who exhibited their ingenious individual call and selecting mechanism; the Union Switch and Signal Co.; the Edison Phonoplex; Wm. Marshall, condensers, the O'Neil and the Chase automatic highway crossing alarms; W. P. Ward, working repeater set; I. N. Miller, protector for telegraph and telephone instruments, and the Dennison automatic telegraph, reproducing autographs, drawings, etc., in fac simile.

NATIONAL ELECTRIC LIGHT ASSOCIATION.

Mr. J. I. Gulick, Chairman of the Committee on Exhibits, has issued a circular to the manufacturers of, and dealers in, electrical apparatus and supplies, inviting them to participate in the exhibition which is to be given in connection with the convention at Montreal. We trust that this invitation will be very generally accepted. The convention will last from September 7 to 11, and it is proposed to carry on the exhibition from September 7 to 16. The large Victoria Skating Rink, 228x110 feet, has been secured for the purpose, and if crowding renders it at all necessary, a large marquee will be put up in the grounds adjoining. The committee hope to arrange for the admission of exhibits into the Dominion free of duty, that is, the duty only being payable if the goods are sold. With the circular go application blanks for space to be filled out and returned to the secretary at 136 Liberty street.

Letters to the Editor.

Notice to Correspondents.

We do not hold ourselves responsible for the opinions of our correspondents.
Anonymous communications cannot be noticed.
The Editor respectfully requests that all communications may be drawn up as briefly and as much to the point as possible.
In order to facilitate reference, correspondents, when referring to any letter previously inserted, will oblige by mentioning the page on which it appears.
Sketches and drawings for illustrations should be on separate pieces of paper.
All communications should be addressed EDITOR OF THE ELECTRICAL ENGINEER, *150 Broadway, New York city.*

THE PROTECTION OF BUILDINGS FROM LIGHTNING.

I WOULD call the attention of your readers to the statement of my position in regard to lightning protection, as made in my paper read before the American Institute of Electrical Engineers, April 21st, which reads: "I would thus formulate what seems to be true—that a conductor which can be easily dissipated by a lightning discharge, protects the building to which it is attached between two horizontal planes, the one passing through the upper end of the dissipated conductor, and the other through the lower end; and it is this one point that I would urge upon the consideration of the Institute." Above the upper end, or below the lower end, of the dissipated conductor there may be damage, but a very careful search of the records has as yet brought to light no case of damage on the same level as the dissipated conductor.

The truth of this could not be better shown than in the case of the church tower at Newbury, Mass., referred to by Mr. C. J. Hubbell, in your issue of June 17th, which is described at length, in Franklin's own words, in my paper. The details of the other cases mentioned by Mr. Hubbell I have not been able to find in my search at the Astor Library; as given in Anderson's "Lightning Conductors, "they have no value as evidence for, or against, my statement, which I believe to be a physical law.

The evidence in my possession of the truth of my proposition in regard to the perfect protection furnished by a dissipated conductor within the limits named is so strong that I no longer have any doubts; but I hope that this question of fact—for I have no theory—will be freely discussed in your columns to the end that the truth, whatever it may be, shall be known, only asking that there shall be a careful avoidance of illogical methods such as were employed by one of the speakers at the Institute meeting.

EDISON INCANDESCENT LAMP LITIGATION.—III.

ARGUMENT OF GEN. S. A. DUNCAN (CONTINUED).

The next morning Gen. Duncan, resuming, said that he desired to call attention to the fact that Dr. Barker's deposition was read from a paper prepared in advance, which it was fair to presume had undergone the inspection of counsel of the Edison Company, and might therefore be regarded as a brief from the other side.

Now, he would ask, was there any invention, on the 21st of October, 1879, in putting a piece of carbon, irrespective of its shape, into a highly exhausted globe made of one piece of glass? Prof. Cross says there could have been no invention in putting a carbon wire in place of the platinum wire of the Edison lamp; no more than there would have been in substituting a superior for an inferior variety of platinum. If to-day a method were devised of making a carbon largely superior to anything that Mr. Edison has made, would invention be involved by substituting the superior for the inferior carbon? He apprehended not.

Dr. Barker, when asked what was the ordinary working vacuum in a commercial lamp, stated it was about one hundred-thousandth of an atmosphere. When asked whether a person skilled in the art wouldn't know perfectly well that in such a lamp any defect arising from a mechanical joint could be obviated by uniting the parts of the glass by fusion, he replied that such a method of obviating the defect would readily suggest itself to a person skilled in the art. In answer to further questions, he said that it was known more than twenty years ago that the best method of preserving the vacuum in an exhausted vessel was to seal by a fusion of the glass.

It seemed to them that the testimony of Dr. Barker, not to mention similar testimony of Prof. Brackett, was enough to dispose of the whole contention of the complainant, that there could have been any merit whatever in sealing up a piece of carbon in an all glass globe in October, 1879.

There were in evidence lamps illustrating Sawyer and Man's methods of sealing their receivers. Lamps had been made, which were used in the McKeesport suit, showing their method of construction; an enclosed chamber with a separate base. These had been exhausted to a high degree and run for 200 hours without impairment of the vacuum. A year later the vacuum was still intact, and Mr. Shallenberger testifies that these experiments demonstrated beyond any doubt, the entire practicability of such a structure. They illustrate the point that it was not necessary to have an all glass globe, in order to have a good working vacuum.

General Duncan said that it seemed to have been assumed in the argument addressed to the Court, and in the deposition of Dr. Barker, that the invention covered by the patent in suit created a new art, and Major Eaton, general counsel of the Edison Company (formerly its president), understands the position of the company to be that it is impossible to make a commercial incandescent lamp without infringing the patent in suit. Was that assumption a tenable one? Was it a fact that that invention, singled out from hundreds of others made by Mr. Edison, and hundreds of others made by other men, is the one thing that has created a new art, or even measurably developed an art which had existed before? Was there any evidence that this invention had ever been applied in a single commercial lamp? Was it true that immediately upon the appearance of this patent, the World recognized that the problem was solved, and that immediately thereafter lamps embodying the invention of this patent went into practical use in enormous numbers? The defendant's position was that the lamp of the patent in suit was a most inferior structure, and made in fact, no more impression upon the art than the platinum lamp of 1878. It was that worthless lamp, exhibited in November or December, 1878, that caused the great panic of gas-stocks in London. It produced a profound impression; gave eclat and notoriety to Mr. Edison, and was never heard of after a few days time, but the lamp of the patent was as worthless, according to their conception, as the earlier platinum one. There was no evidence in the record that a single tar-putty filament, spiral burner lamp, was ever made, or put in commercial use under the patent. It was not until the art had progressed beyond these two worthless things that the world began to appreciate that there was practical value in an incandescent lamp. General Duncan then read a long extract from the testimony of Prof. Chandler, taking in the feeder and main suit, showing that in his (Chandler's) opinion, it was not any of Mr. Edison's lamps that solved the problem of the electric light; it was a system of distribution for which the world had been waiting.

As the result of this consideration of the prior state of the art, Gen. Duncan said that it might fairly be concluded that Edison did not invent the burner of an incandescent lamp; a thing having a small cross-section combined with small radiating surface; nor a thing having high resistance combined with small radiating surface; nor was he the originator of the conception of high total resistance of the burner, which economically affected the question of copper in the mains; nor did plaintiffs believe it was patentable to Mr. Edison to make use of a peculiar kind of carbon which he calls "purely structural carbon;" by a process in which the operation stops when the raw material has been carbonized and nothing is done to increase its density. Nor was it patentable to reduce the raw material to shape before carbonizing it, nor merely to enclose a carbon in an all-glass highly exhausted globe.

The defendants did not believe that Edison created a new art, nor that he discovered a new physical property in carbon; and if they were right in their contention upon those points, they should argue that the only thing new to Mr. Edison, or revealed in this patent, was either his mode of preparing the carbon of the burner, leaving it in that condition of high porosity that contrasts with the old carbons and with the art; or his mode of shaping that carbon into a spiral form, or else his mode of attaching that peculiarly constructed thing to the leading-in wires. They believed that under any plausible interpretation of the patent the invention must be confined to these three matters.

Gen. Duncan said he would ask his Honor to follow him for a little in reference to the claims of the patent and the statements of invention upon which the claims seemed to resent. The term "filament" is not used until the specification comes to a burner made of tar-putty. The invention is said to consist in "a light-giving body of carbon wire or sheets." Neither term is defined in the patent. The French word for the instrument which we call a draw-plate is "filière," and "fil" is the French word for the thing produced by its use; a wire, a thing drawn through a filière; his Honor would observe the analogy between the French words and the English word filament. As the word "wire" is used six times in the patent and the word "filament" only twice, the natural conclusion would be that it is a thing which might be all the way from three or five thousandths of an inch up to a quarter of an inch or even larger. It was, of course, unnecessary to say that the third claim was limited by the precise language of the specification. Now the second paragraph in the statement of invention referred to the peculiar construction given in the first paragraph. "The invention consists in placing *such* burners of great resistance in a nearly perfect vacuum," and so on. What kind of a burner was called for by the previous section? Plainly one that was coiled; coiled not inadvertently, but in pursuance of a well-defined plan, whereby Mr. Edison proposed to secure the two valuable features of construction which he says lie at the very foundation of wide distribution of electric light on the multiple-arc principle; and if we can interpret the claim by reference to this paragraph, his invention consists in putting into that chamber such a burner as is spoken of in the previous paragraph; a burner so organized as to get that high degree of resistance which comes from coiling it, and thus making a part of its radiating surface.

There were three points in claim 1 demanding special attention. The filament is to be made of carbon of high resistance; it is to be made as described, and it is to be secured to metallic wires, as set forth. The witnesses on both sides seem to be agreed that high resistance means high specific resistance, and according to Dr. Barker, the standard by which to measure specific resistance is that of the old carbons. The question then, as regards infringment is whether defendants' burners are made of carbon as high, or higher, than the standard set up by this patent. Are they materially higher than that of carbons that were old in the art? Evidently Dr. Barker, when he gave his testimony, did not suppose that defendants' carbons were of lower specific resistance than the majority of the old carbons, and when, at length, it had been made plain to him that the resistance of defendants' carbons was just about the same as that of the old arc-light carbons, he found it necessary on redirect examination to give a most extraordinary piece of testimony. He said: "Well, a fair interpretation of that language is that the carbon of claim 1 must have a higher resistance than some of the old carbons, but not necessarily as high as others." He tells us he deliberately picked out only the lowest of the old carbons; he says he found carbons in the prior state of the art higher in their specific resistance than the carbon of the defendants' lamps. They should rely, therefore, upon the measurements made by Dr. Morton of prior carbons, in connection with the testimony given in the first deposition of Dr. Barker, in support of the proposition that defendants had no such high specific resistance as that contemplated by claim 1 of the patent. They would contend that the conditions in claim 1 were that the filament is to be made as described, and that it is to be made by "carbonization pure and simple," without any supplemental process that would induce a lowering of resistance. Gen. Duncan supported this position by numerous quotations from the testimony of Dr. Parker and from that of Mr. Edison himself. The other condition, "secured to metallic wires as set forth," in view of the language of the specification, meant the application of a carbonizable plastic material to the joint and carbonizing it in situ. He would next briefly consider whether there was any hidden meaning in the word "filament" which would be of service to the defendant. He would say frankly to the court that he did not know what the word filament meant, but he thought, nevertheless, the plaintiff was committed to certain limitations in regard to it. If the condition of 100 ohms of total resistance when in action is imposed upon this burner by the word filament, then defendants were outside the second claim as regarded two of their lamps. His brother Dyer had almost prayed the court not to construe the limitation of 100 ohms into this patent, because, forsooth, if it should, the Westinghouse Company could not be prevented from going on with some of their low resistance lamps; the plaintiffs could not stop them; they could not kill this industry; they could not destroy the capital which had been invested here. With what grace did an argument like that come from gentlemen who had stood by for five long years, with their hands in their pockets, looking idly on and seeing this great industry grow to its present gigantic proportions; sending out circulars saying, "we own so many patents"—enumerating them—and warning the world not to infringe any of them; not saying "that patent is infringed by that lamp, and we hold you to strict accountability;" offering as an excuse for the delay, what? This: Mr. Eaton, President of the Edison Company from 1881 to 1884, says they knew of the work being done by the United States Company, but that Mr. Edison was too busy in his laboratory to justify him in giving attention to the litigation. They did not think the work the United States Company was doing was sufficient to justify litigation, and they concluded they had better wait until the business had grown to such proportions as to injure the Edison Company; they waited for five years while the United States Company was taking contract after contract away from the Edison Company. In a protest filed with the Secretary of the Treasury of the United States the Edison Company had said that "it was but equity and justice that they should have as many contracts as the United States Company" in lighting the public buildings. The United States Company took from them the contract for lighting the Capitol at Albany and many other conspicuous contracts, and all that time the Edison Company never lifted its finger to bring suit. They come in to-day, after waiting all those years, and say, "Your Honor, don't impose upon this patent the interpretation that the burner is limited to 100 ohms, because if you do, with the methods of distribution known at the present day (although not known then), the Westinghouse Company cannot be stopped." It was not necessary either, according to the contention of these gentlemen, that if the Westinghouse Company was to be killed it should be with this particular club. They had patent 227,229, with a broader claim than this, and other patents, hundreds of them. Logically, therefore, it was not necessary, if that be a legitimate object on their part, that your Honor should sustain the patent on any particular interpretation. Does "filament" mean a burner whose resistance hot is 100 ohms? That is the lowest resistance spoken of in the patent. It had been abundantly established by the testimony of the experts that with any method of distribution known at the date of the patent large numbers of lamps could not have been operated in multiple arc except with a resistance at least as high as 100 ohms hot. This could be accomplished with more recent methods, but the specification must be interpreted now with reference to things then known. Mr. Edison had said in his testimony that his calculations showed that the lamps must have at least 100 ohms resistance to compete successfully with gas. For these reasons, said Gen. Duncan, defendants concluded that the term filament was understood by Mr. Edison to mean a thing having a resistance hot of not less than 100 ohms. What else it may have meant was a mystery to them. They had received no light from the experts, nor from the brief, nor from the argument of plaintiff's counsel. The term never appeared in the art of electric lighting until embodied by Mr. Edison in this patent, and under every obligation which the law imposes upon an inventor seeking the wide protection of the statutes he was bound to define that term with exactness, so that those who did not want to make that thing, but something else, should know what territory was occupied, that they might keep on public land. He had given them a document uncertain, vague and indefinite, and they did not know how to act in relation to it. Left in that condition of uncertainty, they had to do the best they could to find out whether there were some limitations to be imposed upon it. Another definition which it seemed it might be sought by plaintiff's counsel to impose upon the term, that a filament is a thing so small in cross-section that the platinum wire conveying current to it can be sealed into the globe by fusion. They had been told that the old "rods," as Mr. Edison chose to call them, required a wire so large that it could not be effectually sealed into the glass. Here, said Gen. Duncan, is an exhibit, showing seven carbons running from an extremely tenuous one up to one quite thick. Now those largest burners were practically larger than any used in incandescent lamps of the present day. Here, for instance, were a couple of old Sawyer and Man carbons very much smaller than some of those shown in the exhibit (exhibiting). There is a Bernstein lamp and there a Thomson-Houston lamp; they are series lamps, and show burners which he supposed Brother Dyer would say were filaments because they were not rods; perhaps he would say they were rods because they were not filaments, but they were quite large, and he did not know why they should not be called "rods" or not be called "filaments."

Gen. Duncan said he would next pass to the consideration of a certain application filed by Mr. Edison in the Patent Office a little later than the issue of the patent in suit. While the application for the patent in suit was pending Mr. Edison had filed what is known as the "paper-carbon application," in which he had described a burner of paper, and sought to secure a patent on it. A long interference controversy with Sawyer and Man followed, and the latter obtained, as a result of that controversy, the patent that was before Judge Bradley, at Pittsburgh, in the McKeesport suit. Subsequent to the date of the patent in suit Mr. Edison divided off from that application a portion not involved in interference with Sawyer and Man and filed a divisional application, which, having undergone various modifications, is still pending in the Patent Office. It came to the belief of defendants that claims co-extensive with those of the patent in suit, under the interpretation the plaintiff is undertaking to impose upon that claim, were contained in that application. They had called upon the plaintiffs to furnish a copy of that application; they had declined. After various applications to the Commissioner of Patents and to the courts, Judge Lacombe finally had said to the plaintiffs: "You must produce the retained copies of those papers.' Eventually they had been shown and put in evidence. There was very good reason for the plaintiffs withholding the papers; they (the plaintiffs) felt that it was a critical point in their case, and they fought it for a whole year with all the vigor of the able counsel employed to aid them. Among the claims in this application were the following:

"An electric lamp for giving light by incandescence, consisting of a filament of high resistance and flexible carbon hermetically sealed within an enclosing globe made entirely of glass, substantially as hereinbefore set forth."

The Patent Office had rejected the application as not presenting anything patentable over the patent in suit. They did not take the rejection graciously, but said that the claims presented covered vital improvements and advances in the art which had made Mr. Edison's system the success it was. His inventorship had not been disputed and he was entitled to protection therefor. "The invention covered by that patent," said they, viz., "a certain incandescent electric lamp, does not form the essential features of the invention such as is now specifically claimed." To which the Patent Office replied that the claim of both the patent and the application were for substatially the same invention, viz., a high-resistance carbon. Mr. Edison said no, the Edison Company said no. The specification and claims had been drawn by the attorney of the Edison Company; the case was prosecuted by the Edison Company; when he said Mr. Edison he meant the Edison Company. They had made declarations to which defendants could appeal for the porpose of interpreting the patent in suit. They were not satisfied with the declaration of the examiner, and they denounced him later in plain terms. They said: "The claims recite matters of invention original with Mr. Edison; they are useful and important, lying at the very base of the past two years' successful development of incandescent lighting. Mr. Edison, under the law, is entitled to protection therefor. He has not that protection in the patent referred to. It has not been attempted to get that protection in that case. He cannot legally obtain it by reissue of that case. This application is the way to obtain it under the decisions of the court and the Commissioner, and upon the allowance of this application I must insist." A long correspondence followed, in which the office took the position that if Mr. Edison was not entitled to make the claims in a reissue because the public would be defrauded of some of its rights, he was certainly not entitled to claim it in a patent which would cover the same ground as a reissue, and continue two or three years after the original had expired. Gen. Duncan thought his Honor would find, as Judge Lacombe found, that this document was very material to the interpretation of the patent in suit. Not only did this application throw a bright light on the proper interpretation of this patent, but it threw a strong side light upon the laches of the plaintiff in bringing suit. He had referred to the competition that was going on from 1880 to 1885, when this suit was filed The complainants had looked on and said nothing. Major Eaton says the reason was that the defendants were not doing them enough harm; that was simply childish. The explanation of that delay was to be found right here. The Edison Company did not believe during those years that the patent now before the court was the fundamental patent which they now assert it to be. They did not bring suit until that application in the Patent Office had drifted into that position where they felt powerless to secure what they originally asserted under it to be their rights Then they said: "We have nothing to lose by taking our chances on patent 223,898." (At this point the proceedings were adjourned for the day.)

On Monday, June 1st, at the opening of the court, Gen. Duncan resumed his argument, and proceeded to discuss the question of jurisdiction as affected by the statute relating to the limitation of the term of an American patent by a prior foreign patent; which, being a matter of purely legal rather than of technical interest, has been omitted.

In conclusion, Gen. Duncan said that the contention of the defendants in regard to the patent was that it did not meet the stern requirements of the patent law. Mr. Edison did not in his patent describe the invention in such terms as would enable a person skilled in the art to make and use it, nor the best mode in which he had contemplated applying the principle of his invention; nor did he particularly point out and distinctly claim, as required by the statute, the things which he claimed to be his invention or discovery. There was absolutely no definition of the term filament in the patent, and complainants' experts have shown themselves to be utterly incompetent to define it. So of the word carbonization; the patent has not undertaken to specify what that term signifies. What did Mr. Edison mean by carbonization? If but one method was known to him at that time—the old method by the furnace—and that would not answer in dealing with the tar-putty filament which he describes as the best mode of carrying out his invention; then the patent failed, because it was not operative. Mr. Howell had been obliged to resort to a method of carbonizing in order to make his test lamp, which was not known to the art at the date of the patent in suit. Mr. Edison has said in the most explicit language, that electrical heating in a vacuum is carbonizing; that the preliminary work was not carbonizing; it was only charcoaling, and that the real carbonization was done when the electric current was put through the carbon.

It came, therefore, down to this point: Upon the testimony of Prof. Thomson; upon the experiments made by Mr. Howell by the plaintiff; it stood practically confessed by the Edison Company as impossible under this patent to make the thing described, without resorting to practices not known to the art at the date when the patent issued. If Mr. Edison knew that electrical carbonization on the pumps was necessary in order to make a serviceable carbon, he was bound to put it into his patent. Defendants would say further, upon his own testimony, that he did know; because when asked how long he had been carbonizing his burner by that method, he replied, From the very beginning; then he was asked whether the very first lamps made by him in 1879 were so carbonized, and he said, "Yes." Thanking his Honor for his patient attention, he would now yield to his associate.

ARGUMENT OF CLARENCE A. SEWARD, ESQ., FOR THE EDISON CO.

Mr. Seward said that the several large volumes which constituted the record in the present case were, to phrase it mildly, professionally repellant, and he did not know but that they might be judicially repellant also. His friend Mr. Duncan, even in the zeal of his presentation had suggested that he did not expect his Honor to read, page by page, the 5,000 pages which constituted this record. This prolixity had arisen from the fact that the professional experts, sometimes called by the authorities "auxiliary counsel," had here met with professional gentlemen almost as expert as themselves. When, therefore, these experts were upon the stand, they had advanced theories, and had submitted to be cross-examined to sustain theories to an extent which was wearisome, cumbersome, and not enlightening in reference to the two questions which actually present themselves for adjudication. One of these was, is the Edison patent valid? and the other, did the defendants infringe it? Those were the two questions of fact; whether the patent was valid upon its face, whether it described sufficiently the modus operandi, the construction or other purpose for which it purports to have been issued; these would be discussed by his brother Lowrey, but he wished to call his Honor's attention to one statement of the Supreme Court, to wit:—"Experts may be examined to explain terms of art, but cannot be received to prove to the court or jury what is the proper or legal construction of any instrument or writing. A judge may obtain information from them, if he desires it, on matters which he does not clearly comprehend, but cannot be compelled to receive their opinions as matter of evidence." Hence much of this record would disappear, not containing matters of evidence with which his Honor need trouble himself, but only expressions of opinion from "auxiliary counsel." These expert depositions, occupying so much of the record, invited an excursion into the electrical field too broad for him to attempt to cross. There had been assigned to him (Mr. Seward) a question of fact, and such answer as there might be to the questions of law presented by the defence. He desired first to submit some general views of the case indicating the drift of the inquiry to be made by the court. He submitted with some confidence, that his Honor had not been shown, either in the art or in antecedent patents, one which covered this invention with the exception, as he would hereafter show, that he would be expected to find the invention of Mr. Edison, in the Sawyer and Man discoveries, inventions, patents, labors and experiments. On the question of utility, the patent itself was *prima facie* evidence, and so was every incandescent lamp ever used; somebody had evidently made an invention which rendered incandescent lighting possible, and who ever made it ought to have the credit of it. Every successful lamp had a burner of filamentary formation, small in cross-section and radiating surface; of high specific resistance; of sufficient stability to resist disintegration to an extent rendering a lamp useless; having sufficient elasticity to resist shocks, and capable of expanding by heat without injury to its substance. Such a burner was placed in a permanent vacuum in an all-glass chamber, and connected to platinum wires leading out to the wires which supplied the current. Each of these features had been purposely originated by Mr. Edison, or by him selected from the arts as a unit for his intended combination. By this invention, for the first time, the practical subdivision of the electric light, and its use in multiple arc had been successfully accomplished. Did Mr. Edison make this invention? If he did, his patent was not obnnoxious to the criticisms which had been made upon it. It was valid because he was the original and first inventor of that which usage demonstrates to be useful. No one else had claimed to have been the inventor of this lamp except Sawyer and Man. What was it that had been needed in all the prior lamps to make any one of them a successful lamp? The complainants contended that it was Mr. Edison's filamentary burner of carbon, arranged and combined as he arranged and combined it in his patent. His Honor would find in all this voluminous record, no allusion to a filamentary burner combining high specific resistance with small radiating surface. It had not been described, nor known, nor produced. The fact of success in incandescent lighting confronted his Honor as an admitted fact, and the further question of fact for him to determine was whether such success was due to Mr. Edison's invention, or was not, and if not due to Mr. Edison, to whom was it due. No answer to that inquiry had yet been given, apart from Sawyer and Man, by his ingenious friends upon the other side. The art was absolutely silent. The complainants asserted that success was in the lamp, and not outside of it; after that success had been obtained, the field was open for improvements in dynamos, converter systems, and all else that had since been done, and only done, for the purpose of utilizing the successful lamp which Mr. Edison had given to the world. The experiment of Fontaine, which had been exhibited by Mr. Dyer, had proved that whatever had produced the perfect light in one case and the defective light in the other, had been due solely to what there was in the globes, namely, the different forms of carbon used.

He came next to the Sawyer and Man patent; that was the only resource for his Honor if he was going to find that this invention was useful, and that it had not been made by Mr. Edison, because if his Honor did not find it in Sawyer & Man, he would not find it in prior patents, in general literature, nor in specific facts. Some 900 pages of the record had been devoted to what Sawyer & Man did. According to their own statement, there were not in the years 1877 and 1878, two more intelligent, accomplished, universally read electricians than Albon Man and William E. Sawyer. They knew everything from Crookes' radiometer and the Geissler tube, down to Lane-Fox inclusive. Nothing in the whole field of electrical science, produced in experiment or handed down by tradition, nothing which had been made in France, England or America that they did not know.

The defense, upon the answer, says that the alleged invention of Mr. Edison was known to Sawyer & Man; that it had been described in their prior patents, and that Edison had surreptitiously and unjustly obtained a patent for that which had been invented by them, and that they were using reasonable diligence in adapting and perfecting the same. So that when Sawyer and Man had made their incandescent lamp, which defendants' answer virtually alleged that Mr. Edison stole, it was an invention; but when complainants put it forward as Mr. Edison's invention, then defendants say it was no invention at all; that it never rose to the dignity of an invention. Thereafter, in May, 1885, Sawyer and Man had procured for a fibrous arc-carbon in an incandescent lamp, a patent which had been applied for on the 9th of January, 1880, and upon that patent they had brought suit in the McKeesport case. They had produced here three lamps in which His Honor was to find Edison's combination and invention.

Mr. Seward then went on and read extracts from the testimony showing what Sawyer and Man did, which, as it is substantially the same as that discussed in the McKeesport case, need not be recapitulated in detail. Commenting upon the evidence, he said that the only practical question with which he would trouble His Honor was this:—"Did Sawyer and Man, in their efforts to produce a burner of any sort, succeed in producing one which could be successfully used, of a filamentary form having a small cross-section with small radiating surface and high resistance?" Referring first to the meaning of the word "filament," Mr. Seward said that to both the educated and the uneducated mind, if the latter had some knowledge of electricity it conveyed a sufficiently accurate idea of what it was intended to describe. His brother Lowrey would pardon him if the suggestion came from him (Mr. Seward) as to what he thought a "filament" was. It was a sufficient quantity of carbon to represent a word, in itself indicative of degree, having a small mass; small cross-section, and sufficient specific resistance to accomplish the purpose which Mr. Edison intended of giving light by incandescence. Anything which did that and had those characteristics, was in his judgment a filament. Quoting from the testimony in behalf of Sawyer and Man, in which it was stated, among other things, that all their carbons were treated, for the purpose of making them more dense and of diminishing their resistance, Mr. Seward said that it clearly proved that it had not been the intention of Sawyer and Man, in seeking to make a practical incandescent lamp, to use a burner with high resistance. They were not traveling in the path in which Mr. Edison was traveling; they were not seeking to do what Mr. Edison was; namely—to find a carbon which should be stable in form and would remain stable under the heat of the current. Sawyer and Man had not set out to produce Mr. Edison's carbon burner. They did not meet with it accidentally. They never made it; never used it; never claimed it; and if they did not, no one else whose name has been alluded to in connection with incandescent lighting did make, or use, or describe it.

He would next say a word or two upon the law. The argument of the defendant had carefully avoided what was really the most important law-point in the case. The position that plaintiff had so acquiesced in what defendants had done, as to lose its right to an injunction, even were the patent valid and violated by defendant, had been sought to be taken in the evidence. The patent in suit had been issued in January, 1880; this suit had been commenced in May, 1885. The only overt act charged against the plaintiff had been that it had not sooner commenced the suit. If there were anything in that defense it should have been pleaded; not having been pleaded it could not be availed of at any time or for any part of the suit. The injunction would go on or not according as his Honor found upon the issues raised in the pleadings. But as a matter of fact there had been no laches nor acquiescence. During that interval of five years the plaintiff had been under a cloud; so deep, so dense, and apparently so permanent, that even the bringing of a suit in 1885 was apparently premature. In a patent suit, which drags its slow length along, two or three years was insufficient to prepare for a contest like the one now pending. The cloud under which the plaintiff had been resting had been created by the then existing decisions, declaring the effect of a prior five years Canadian patent. Under the law as it then stood, the American patent would have expired with the five years' life of the Canadian patent. Their suit had been met with that plea, which his Honor had sustained, and it had taken two years to get through the Supreme Court with the Bate case, in which it had been decided that the patent in suit had not expired. Therefore plaintiff's suit had been premature as it was. In the meantime the defendants knew that plaintiffs had not been idle; that they had prosecuted suits in France and England, and that knowledge was known to Mr. Hebard, the president of the defendant company. His Honor would further perceive that the defence of acquiescence of necessity implied acquiescence on the part of the defendants in the validity of the patent. A man could not ride two horses in different directions at once. They might either plead acquiescence or invalidity. Mr. Seward then read from the opinion in *Williams* vs. *Boston and Albany Railroad*, to show that mere delay or acquiescence could not establish an abandonment or dedication of the patent. Mr. Seward then referred at some length to the contention of the defendants, that a subsequent Swedish patent which had been granted on its face for a term of 14 years had expired and that it had the retroactive effect to kill the prior Canadian patent, and through that to kill the patent in suit. He contended that the Swedish patent had not expired, even under the Swedish law, and that even if it had done so it would not necessarily have affected the Canadian patent. Mr. Seward also considered the defence that after the suit had been brought the complainant company had consolidated with the Edison company for Isolated Lighting and had thereby become incapacitated to prosecute the present suit. He argued that Judge Shipman and Judge Wells had already decided elsewhere, in suits commenced prior to the consolidated proceedings, that such suits had not been interfered by them in any way.

Mr. Seward said he would make one or two other suggestions, which perhaps seemed to present a point of law. Defendants had asserted that the discovery of Mr. Edison was not an invention, but a mere product and result of electrical engineering. He agreed that what Mr. Edison did was "engineering" provided that word was used in its proper sense, which he conceived to be a derivative sense. Its base or root was the Latin *Ingenium*, from which the English word word "ingenuity" was derived; defined by Stormont as "the superior power of invention." In that sense, and in exercising that power to produce this incandescent lamp, Mr. Edison was, in the highest and most impressive sense of that word, an "engineer;" one who exercised "a superior power of invention."

It had been strongly urged in the able argument of his brother Duncan, that it did not require anything beyond the application of known rules of electricity to produce what Mr. Edison had produced. Unable in their own minds, as every one was, to separate the knowledge of to-day from the knowledge of 1878, what had been done seemed to-day to be so evidently plain, simple and easy, as not to require any exercise of the inventive faculty. His Honor knew how placidly and gently Judge Blatchford conducted himself, and how seldom he employed the language of sarcasm, but in a similar case he had used these words:—"It is easy now, after the event, for scientific men to say with the knowledge of to-day that the thing was obvious, but the crucial facts contradict the assumption." What were the crucial facts here?

(1). There had been a pressing necessity for a successful incandescent lamp. The ingenuity of Sawyer and Man had been directed to gratifying it, but until Edison had given to the world his attenuated burner in a vacuum, the necessity remained unfilled. (2). The literature of the art; the record of past experiments, would have deterred any less courageous, less persistent, less confident inventor, than Mr. Edison, from making any further experiments with carbon. But he had put aside the experiment of others; the instruction derived from literature; and traveling in his own way, to his own end, he had found that carbon could be produced in such a manner that it would be stable and sufficient for the purposes of a commercial lamp, and he had given that to the world as his contribution to the science of incandescent lighting.

ARGUMENT OF MR. F. H. BETTS FOR THE UNITED STATES COMPANY.

Mr. Betts said his associates had requested him to examine the foreign decisions, and to point out how far the state of facts developed in the present record called for a different interpretation of the patent in suit at the present time. Complainants contended that all incandescent lamps made prior to 1878 were of no commercial importance; that when carbons were used they were brittle and destructible, and that the resistance of the lamps was so low as to render them incapable of being assembled in numbers with any commercial success. They pointed to the fact that the experiments of Fontaine had proved, as he conceived, that the consequent loss was so great that the scientific world had accepted his conclusion that it was impossible to subdivide the electric light He might say in passing, however, that this belief was not universal. Complainants had asserted that the lamps of Sawyer and Man had been brushed away by the decision of Mr. Justice Bradley. Mr. Seward had contended that they were of no importance, because they were of low resistance. They had admitted that in 1878 Lane-Fox had shown an appreciation of the necessities of the problem, but alleged admissions by him were quoted, as tending to show that he himself conceded priority to Edison in the production of a commercially successful lamp. He would only say in passing, that it did not appear that Lane-Fox was speaking of lamps made in accordance with the patent in suit, but of the later lamps of Mr. Edison, which were successful, for instance, the bamboo carbon lamp. Complainant asserts that the present patent describes and claims the invention which rendered incandescent lighting practicable; that Edison appreciated the neccessity, for commercial reasons, of making a burner of high resistance and small radiating surface, and that he discovered the indestructibility of carbon in high vacuum and hence used it for such a burner. On those two points, as he understood the opening argument of the complainants, this invention of Mr. Edison was supposed to rest, and the present patent, if sustained at all with a broad construction, is to be sustained on account of those two features.

Turning to the foreign decisions, his Honor would find that the course of litigation had been one of alternate success and failure. He thought his Honor would be struck with the fact that even in those decisions in which the patent was sustained it had been sustained with considerable hesitation. Mr. Justice Fry, speaking of the sufficiency of the specification had said:—"This description is so far from being as clear as it might be, that we at one time doubted whether it was not studiously and wilfully obscure, but on further consideration we are not prepared to hold such to have been the case, *especially as the point was not urged by the appellants*." The courts were also very doubtful in coming to a conclusion upon the question of novelty, in view of the earlier experiments of Swan. The carbon which Swan used was of considerably larger size than that describ ed in the Edison patent, or the one now commonly known as a filamentary carbon, yet the justices were inclined to hold that it was very much a question of mere degree in the attenuation of the carbon; if it had been wholly a question of degree he believed that they would have held the patent invalid. If the English decisions were to be regarded as of any authority upon construction, he would point out that the first claim was not infringed by the lamp involved in the present case. As to the second claim Justice Butt said that the infringement depended upon the meaning of the words "carbon filament;" if it meant a carbon filament made as described in the patent, there was no proof of infringement, but the justice held it to mean *any* carbon filament, however made, possessing certain properties mentioned in the specification; it must possess flexibility and resilience; it must be of small cross-section, of high resistance and presenting but a small surface from which radiation could take place. He (Justice Butt) was disposed to think, while refraining from a decided opinion, that the resistance must not be less than 100 ohms. The appellate tribunal had construed the claim in somewhat broader terms. Criticizing the vagueness of plaintiff is interpretation, its conclusion was that the claim ought to be construed with generality, and hence might be paraphrased as a claim to every combination of any carbon filament with any receiver entirely of glass through which leading wires passed and from which the air was exhausted. The qualification of Mr. Justice Butt that the filament must be one that has flexibility or resilience was apparently disregarded. The court had considered that high resistance was an essential feature, for in the prevailing opinion of Mr. Justice Fry he had said:—"Mr. Edison used a filament instead of a rod for a definite purpose, and by the diminution of the sectional area made a physical law subserve the end he had in view. The smallness of size, therefore, was no casual matter, but was intended to, and did bring about a result which the rod could never produce, and so converted failure into success." He (Mr. Betts) thought that was as forcible a statement as could be made of the argument in favor of the patentability to Edison of the feature of high resistance in the filament. But then immediately came this trouble :—Does it mean high *specific* or high *total* resistance? If it was contended that it was high specific resistance, the discussion might as well stop where it is, for the whole case might be easily disposed of. Of course, complainants could not insist that a burner had high specific resistance merely because it is of carbon. Any burner of carbon was of high specific resistance as compared with one of platinum. But Edison could not claim each and every burner of carbon in an exhausted glass vessel, for that was all. If high specific resistance was essential, it must mean that it was due to some particular kind of carbon, which had, relatively to other kinds, high specific resistance. If that were the contention, and it seemed to have been emphasized by his brother Seward all through his argument, there was no need to discuss the case further, for defendants did not use burners or carbon of high specific resistance. If the Edison patent was construed to be for a lamp with a burner of a particular carbon that has high specific resistance, then defendants' lamp did not contain that carbon. As pointed out by his brother Duncan, he thought there was strong ground for saying that the Edison patent did mean that very thing. If they took Edison's words, his plain statements, and gave them their legitimate interpretation that was what his patent was limited to, and that was what the defendants did not use. He thought, however, that that was not the meaning of the English court. They considered that the filament must have great total resistance to achieve commercial success, but then they were immediately met with the question, What was "high" total resistance? It could not mean high resistance relatively to the circuit, because every prior lamp, from the very law of its operation, must have had a burner of high resistance, relatively to the rest of the circuit. Did it mean high resistance, in the sense of being relatively higher than the old lamps mentioned in the patent? It might be contended that the English court thought that Edison meant to include all lamps having a higher resistance than 4 ohms. In that sense a lamp with 5 ohms or 10 ohms resistance would be a high resistance lamp. The difficulty about that construction was, that Mr. Edison was mistaken if he supposed that no lamps had been described having more than 1 to 4 ohms resistance. Mr. Betts then read from the Sawyer and Man patent of 1878, pointing out that the whole subject of arranging lamps, both in multiple arc and in series, had been there described, and the use of lamps having 10 ohms of resistance referred to. He cited this patent to show that Edison could not say that every lamp of more than 4 ohms resistance was a "high resistance" lamp. What other definition was left of high resistance? Only this: that the resistance should be *so* high as to enable the lamps to be commercially used in large numbers in multiple arc, and that meant substantially in figures, as proved on both sides of the case, that each lamp must be 100 ohms. He thought that was the meaning the English court put on the term of high resistance in the English patent. Certainly it had been so in the first case before Mr. Justice Butt, and on appeal. It seemed to him that in the second decision the court had felt that there was much difficulty about the question and that it was simply a question of degree. The justice who pronounced the prevailing final opinion on the final case defined the term "filament" as a carbon which had been bent before carbonization into the required form, and had been carbonized while so bent. In other words, it had been held that the patent should stand when limited to a carbon filament made in a particular way. He thought it was doubtful whether the defendants would infringe on any such construction as that.

The defendants' carbons were not bent, but were stamped out of sheets by dies into the forms desired. Whether or not this was the equivalent of bending, would be for his Honor to determine. Another difficulty was that our courts were not inclined to limit a claim for a product, when claims were made generally to a product made by a particular process, unless such construction appeared perfectly clear from the words of the claim. The English court, in dealing with the Swan defense, had overruled it on the ground that what Swan did was not a commercial success, but Mr. Justice Fry, in the opinion reversing Mr. Justice Kay, had said that if Swan's lamp had been a success instead of a failure, it would, in his opinion, have been an anticipation of the plaintiffs' patent. His efforts to improve his lamp had showed that he was not thinking of filamentous carbons but of other matters: still his lamp had given light for a time, and was very near, though in his opinion not quite, an anticipation. His Honor would find that the English courts had sustained the second claim of the English patent, because in their opinion it had two characteristics distinguishing it from prior lamps. One was, that the resistance of the filament was so high as to give commercial success when large numbers were used in multiple arc, and the second, that the bent carbon was a limitation, and that form must be produced by bending first and carbonizing afterward. It did not appear in the English cases that anybody had anticipated Edison on those two points.

Looking at the contention in the present case, he would next compare the evidence with the arguments of counsel. because some of the arguments were not supported by the evidence. Great stress had been laid upon Edison's appreciation of the fact that high resistance and small radiating surface were essential. Indeed, his brother Lowrey had at one time said that the making of filamentary conductors of high resistance was the whole of the invention. Now on that, which was the principal point in their case, complainants had produced two of the most striking exhibits he had ever seen. One was the exhibit of Fontaine's experiment and the other the exhibit showing the comparative sizes of conductors. The Fontaine exhibit was a problem of distribution, not a question of the use of carbon. So far as the exhibit had illustrated the advantages of high resistance, it had been entirely irrespective of the material which produced the resistance. Platinum burners would have done exactly the same. It had illustrated not only the utility of high resistance irrespective of material, but the necessity of a system of distribution by which enough current was supplied for all the lamps. The illustration of the comparative sizes of conductors required for high and low resistance lamps was a beautiful one, but it had nothing to do with the use of carbon conductors. It simply illustrated the fact that the higher the resistance the less current was needed, and hence the smaller the conducting wires might be, and in that respect no doubt high resistance in lamps was at the bottom of commercial success.

His Honor would remember that the English court sustained this patent on the ground that it was for a high resistance lamp with bent carbon. But upon the present record the complainants could not, and did not rely upon either position; they might in argument but they did not in the record. In his French patent Edison had exhausted the patentability of high resistance. It had not appeared in the English case that Edison had previously patented a high resistance lamp, and had fully explained where the difference lay between commercial success and failure. If one operative platinum lamp had been made containing the principle of high resistance and could, as the plaintiffs have alleged, have been used for the very purpose that the carbon lamps were being used, the reduction of the amount of material in the conductors, thereby giving the lamp the element of commercial utility,—it did not make any difference whether only one was made, or whether there were 50 made; it was an operative lamp.

The complainants' experts themselves have testified that high resistance was not an essential of the lamps of the present patent. Prof. Barker had said that not high total resistance, but only high specific resistance was important. Mr. Clarke had said that in his opinion the patent was not necessarily limited to lamps having a resistance high enough to make them suitable for use in multiple arc. They say that if a lamp has 10 ohms, or even five ohms, it comes within the patent. Mr. Betts then exhibited a sample case of Edison lamps, all of which were stamped with the number of the patent in suit; some of them were only half an ohm resistance. It was simply a question of size. Those with a fraction of an ohm resistance were claimed to be as much within the patent as anything else.

The idea of making carbon conductors of high resistance was obvious prior to Edison's patented invention. Mr. Clarke had admitted that in June, 1879, resistance was simply a question of where the lamp was to be used, and that anybody skilled in the art would know that was true of carbon as well as of platinum. Mr. Clarke's testimony had pointed out the only direction in which invention could have been exercised, and that was in finding some way in which a durable carbon could be made. That was all there was left in the case. Neither could complainants rely upon the other point on which the English courts had sustained the patent; the bent form of conductor; that was old, on evidence apparently not discussed before the English courts. Sawyer and Man had done it in 1878 if nobody else had done it earlier. In fact, Mr. Justice Bradley seemed to have disposed of that contention, for he had said in his opinion that it was old even before their day.

Sawyer and Man's lamps had been put aside by Mr. Justice Bradley as having been on the wrong principle; as having been low resistance lamps; and his brother Seward had devoted the morning to proving to his Honor that their lamps were low resistance lamps.

That was perfectly true, but then complainants' experts had admitted that the patent did not call for a high resistance lamp, nor for one suitable to be commercially used in multiple arc. That feature of the case had been, in the evidence, abandoned. He could hardly resist the conclusion that if the English courts had the proofs before them as in the present case there would have been nothing left of the basis on which they proceeded, and if they had sustained the claim at all it would have been on some narrower construction. Now, that was the exact state of facts that had appeared in the German case, and the consequence had been that the highest court in Germany, subsequent to all the English decisions, had held that Edison must be limited to the specific thing described; a coiled carbon incandescent conductor in which high resistance was combined with a small radiating surface by masking a part of the light. The fact was, that the only real invention that could be made when Edison took up the carbon lamp, was to show how to make a durable carbon, and this he had not described in his patent in any way which had advanced the art. (At this point the court adjourned for the day.)

THE ADAMS ELECTRIC RAILWAY CLAIMS IN SUIT.

The Adams Electric Co., of St. Louis, through Dr. Wellington Adams, whose patent and claims were lately described in THE ELECTRICAL ENGINEER, has brought suit for infringement against the Lindell Railway Co., of St. Louis, which has been using Sprague motors and apparatus. It is claimed that in these motors the principle of conveying power to the axle and the method of flexible suspension of motor and gear have been infringed. The suits will, it is understood, be defended by the Edison Co. which now owns the Sprague patents.

SHORT VS. WESTINGHOUSE ELECTRIC RAILWAY LITIGATION.

A special dispatch from St. Louis of June 19, says: "The telegraphic news this morning contains advices of an electric patent suit instituted in the United States District Court at Pittsburgh, Pa. The suit is brought by the Short Electric Railway Company, of Cleveland, Ohio, against the Westinghouse Electric and Manufacturing Company for alleged infringement of patents owned by complainants on gearless electric motors, both parties to the suit having their motors now in operation in Pittsburgh. The suit has a strong bearing on the suit brought in the United States District Court in this city only last week, and will become a phase of the same fight. The Adams Electric Company, of St. Louis, will next week ask to be made codefendant with the Westinghouse Company in the suit for infringement brought by the Short Company. It will also, at the same time, institute suit against the Short Company for infringement of a patent issued to Dr. Wellington Adams covering the gearless-motor principle.

"The officers of the Adams Company of St. Louis, claim that this action on their part is precipitated by the beginning of the Short suit. They charge that the proceedings just begun in Pittsburgh are in reality a friendly litigation between the Short and Westinghouse systems, intended to secure adjudication on certain points of their own which would materially strengthen their positions as defendants in the suit that was to have been brought by the Adams Company, following a decision in its present suit against the Sprague system. The local electric patent claimants also charge that the suit of the Short Company would never have been brought had it not been for the opening of the Adams suits in St. Louis. It is evident that a great fight over electric motor patents is just begun."

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED JUNE 16, 1891.

Accumulators :—

Secondary Battery, D. Tommasi and C. Theryc, 454,091. Filed Nov. 10, 1890.
Principal feature consists in the form of the electrodes, which are tubular instead of in plate form.

Secondary Battery, J. S. Sellon, 454,187. Filed April 26, 1887.
Claims a plate or support containing an alloy of two metals and an amalgam thereof; also claims the above in combination with active material.

Alarms and Signals :—

Electric Signal for Mine Shafts, F. W. Bacorn, 454,018. Filed Sept. 2, 1890.

Signal Indicating Apparatus, J. O. Ziegler, 454,245. Filed Nov. 28, 1890.
Improvement upon the signaling apparatus patented to the same inventor Sept. 16, 1890, No. 436,371.

Conductors, Conduits and Insulators :—

Insulated Electric Conductor, E. D. McCracken, 454,060. Filed March 5, 1891.
Wraps the conductor with strips or ribbons of paper folded longitudinally so as to secure several thicknesses in one winding.

Subway for Electric Wires, W. Readman, 454,155. Filed July 26, 1891.
Forms a series of channels in the curbing along the side of the roadway or street.

Connector for Electric Wires, E. L. Nash, G. G. Stout and J. R. Davis, 454,181. Filed Jan. 20, 1891.
A tubular connector is provided with a sheath of insulating material through which pass thumb-screws with insulated handles.

Wall Fixture for Electrical Conductors, O. H. Pieper and F. M. Watson, 454,226. Filed Nov. 5, 1890.
Especially for use in securing conductors where they pass through plaster walls or similar supports.

Tubular Electric Conduit, E. H. Johnson, 454,275. Filed Sept. 15, 1890.
Two or more series of tubes are placed one over the other, always breaking joints; a cementing material is employed between the several tubes, thus making a continuous conduit.

Distribution :—

Transformer, E. Thomson, 454,090. Filed Oct. 11, 1890.
Claim 1 follows:
The combination, with a rectangular sectional core having two of its sides covered by the primary and secondary coils wound thereon, and its other sides flush with the ends of the coils, of the closed iron frames of magnetic material surrounding the core and coils and completing the magnetic circuit.

Dynamos and Motors :—

Electric Motor, H. H. Blades, 454,024. Filed May 11, 1889.
Details of design and construction intended to secure simplicity and compactness; includes means for correctly balancing the armature after it is completed and wound.

Dynamo Electric Machine, R. Eickemeyer, 454,336. Filed June 15, 1888.
A drum armature is so constructed and wound that when finished the ends of the armature are flat and substantially rectangular to the axis. The patent includes special constructions of field-magnets and of the commutator.

Electrolysis :—

Process of Electro-Deposition and Cathode Therefor, A. C. Reinfeld, 454,381. Filed Mar. 8, 1889.
For galvano-plastic deposition. The cathode or receiving surface is formed of nickel alloy, and has its surface oxidized, polished and filled with a soap-like mixture.

Galvanic and Thermo-Electric Batteries :—

Galvanic Battery, W. Macmillan, 454,057. Filed Oct. 17, 1890.
Porous cup is a perforated vessel of stiff fluid-resisting paper; a covering of fibrous material is applied.

Lamps and Appurtenances :—

Incandescent-Electric-Lamp Controller, J. J. Fanning, 454,038. Filed Nov. 4, 1890.
A rheostatic apparatus for regulating the brilliancy of lamps for scenic exhibition.

Mast-arm for Electric Lamps, T. Dillon, 451,166. Filed Jan. 19, 1891.

Electric Arc Lamp, P. Clarke, 454,253. Filed Feb. 13, 1890.
Employs the expansion and contraction of a thermo conductor for actuating the regulating mechanism.

Incandescent Lamp Filament, T. A. Edison, 454,252. Filed Oct. 27, 1886.
Claims filaments formed from the hard central portions of the root of plants, especially plants of the palm family.

Electric Arc Lamp, S. W. Rushmore, 454,294. Filed Dec. 10, 1890.
Relates to the feed-regulating mechanism; employs a yielding follower upon one of the carbons.

Electric Arc Lamp, S. W. Rushmore, 454,295. Filed Feb. 16, 1891.
Relates to feed-regulating mechanism.

Electric Arc Lamp, J. E. McAuley, 454,443. Filed Apr. 21, 1890.
Details of feed-regulating mechanism.

Measurement :—

Electric Resistance Box, R. Eickemeyer, Jr., 455,207. Filed Feb. 16, 1891.
Relates to the construction of resistance boxes and particularly to the rigid and secure support of the coils and their insulation.

Electric Current Indicator, A. B. Herrick, 454,270. Filed Oct. 16, 1890.
Intended particularly for an ammeter. Employs a solenoid and movable core connected with an index hand; the solenoid is composed of several coils which can be joined up in series or in other relations by means of a commutator; the scale is marked in sections, indications at each section being appropriate for some one arrangement of the coils.

Medical and Surgical :—

Electric Apparatus for Treating Deafness, G. F. Webb, 454,313. Filed Apr. 21, 1891.
A device for applying current through the ear by means of a circular-shaped electrode.

Miscellaneous :—

Electric Switch, H. T. Clark, 454,081. Filed Apr. 15, 1891.
A rocking-lever switch.

Electric-Locked Switch, F. Teague, 454,087. Filed Dec. 15, 1890.
Adapted to insure a safely-locked connection combined with a quick break when disengaged.

Controlling Mechanism for Elevators, W. O. Wakefield, 454,095. Filed Aug. 6, 1890.
With an elevator worked by an electric motor a plunger working within a cylinder and connected with a regulator of the motor; is controlled by a valve mechanism under the hand of the attendant.

Electric Pole in Gas or Vapor Explosive Engines, F. E. Tremper and J. W. Eisenhuth, 454,238. Filed July 31, 1890.
Adjustable electrodes within the cylinder for ignition.

Apparatus for Sewing Carpets, F. Ames, 454,404. Filed Feb. 20, 1890.
Employs an electric motor mounted, with a sewing machine, upon a traveling carriage.

Method of Making Binding Posts, E. T. Greenfield. 454,430. Filed Dec. 16, 1890.

Railways and Appliances :—

Electric Railway Car, E. M. Bentley, 454,020. Filed Mar. 26, 1887.
Claim 1 follows:
The combination of the truck-frame mounted upon the axles independently of the car-springs, the electric motor supported beneath the car-body on the frame, the countershaft having substantially rigid bearings on the frame with the motor and driven by the latter, and the car-axles having substantially rigid bearings with the counter-shaft and driven therefrom by means of a connecting-rod.

Electric Motor Car, E. M. Bentley, 454,021. Filed June 13, 1888.
The motor is journaled on an axle of the truck with its armature uppermost and extending above the floor of the car-body.

Conduit for Electric Railways, E. M. Bentley, 454,022. Filed Sept. 8, 1888.
Employs for one of the slot rails of the conduit a form which may be used at the same time as one of the track rails.

Electric Railway, F. O. Blackwell, 454,023. Filed Oct. 22, 1890.
Claim 1 follows:
The combination, in an electric railway, of a supply conductor and rail-return with an accessible bare supplementary conductor connected electrically with the rails for increasing the conductivity of the return branch of the circuit, and in contact with which the travelling motor also is maintained.

Conduit for Underground or Subway Electric Systems, J. J. Miller, 454,177. Filed Feb. 14, 1891.
Details of supporters and insulators for the conductor.

Motor-Car for Underground Electric Systems, J. J. Miller, 454,178. Filed Feb. 14, 1891.

Relates to the trolley; a laterally movable slide carrying the trolley arm, which is provided with a flat guide plate to operate in the conduit slot.

Electric Head-Light, R. Pattison and D. G. Desmond, 454,184. Filed Dec. 9, 1890.

A lantern for street car head-lights.

Electric Block System for Railways, A. H. R. Guiley, 454,344. Filed Feb. 11, 1890.

The locomotive carries a pendant contact-lever adapted to engage contact-pieces along the track.

Current-Collecting Device, R. M. Hunter, 454,487. Filed Dec. 18, 1889.

The trolley arm is formed of a tube of gradually decreasing diameter.

Telegraphs :—

Electric Telegraphic Apparatus, S. V. B. Essick, 454,338. Filed Jan. 12, 1891.

A relay or receiving instrument for use with reversed currents.

Telephones and Apparatus :—

Bi-Telephone, E. J. P. Mercadier, 454,138. Filed Feb. 27, 1891.

Two receivers are made of very small weight and adapted to be carried while in use on the head of the operator, one at each ear.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

When you advertise, say something that will stick.

THE INCANDESCENT LAMP MANUFACTURERS' ASSOCIATION.

A MEETING called for the purpose of effecting an organization of incandescent lamp manufacturers was held in the Astor House, in this city, on Wednesday and Friday of last week, at which about fifteen lamp manufacturing companies were represented. A permanent organization was formed under the title given above, and the following officers were elected pro tempore: President, J. H. Cooke, Sunbeam Lamp Co.; recording secretary, O. K. Stuart, Germania Incandescent Lamp Co.; corresponding secretary, J. W. Peale, N. Y. & O. Co.; treasurer, Mr. Babcock, Buckeye Lamp Co.

Various matters connected with the trade and lamp litigation were discussed. It was agreed to give a uniform guarantee of 600 hours' average life or 100 hours for each individual lamp. It was also resolved to fix 70 cents as the price for lamps in small lots, and to scale the price down to 50 cents for large lots; sales to be made on 30 days strictly, and allowance of three cents to be made on bases returned.

The action taken at this meeting is to be confirmed at another meeting to be held at the Astor House on July 17, when it is expected that a fuller representation will be on hand. No representative of the Edison, Sawyer-Man, or Thomson-Houston Cos. was present, though it is understood that some of these will join the association later on.

THE CROWDUS CHEMICAL ELECTRIC CO.

The above company, of 230 Main street, Memphis, Tenn., operating under the patents of Mr. W. A. Crowdus in the manufacture of primary batteries for constant current and constant potential work, has now issued its catalogue and price list. It is a handsome pamphlet of 34 pages of text and illustrations, and furnishes a very full description of the apparatus brought to notice. Some of the devices have already been illustrated in the columns of THE ELECTRICAL ENGINEER. The Crowdus Co. believe that there is a very large field for primary batteries in the supply of light and power where dynamo current is not available; and instead of making any of the usual wild or absurd claims as to what they can do, they show their apparatus, give details of the cost of zinc and sulphuric acid, and give the discharging rates of each class of cell, so that any one can ascertain for himself the number of watt hours, and the cost per charge of the battery or per day. The company is supplying very neat and ingenious lamp outfits, so arranged that the lamp makes the necessary connections on being placed on the ornamental battery box, which serves as a pedestal, and which carries a charge more than equal to a full evening run. In another form the same idea is very prettily worked out in a piano lamp. The batteries and special ornamental boxes can be obtained separately, as in fact can all the various parts. In the power line, the company uses the Perret small motors of the Elektron Co., as well as one or two simple forms for turntable work for store windows. With the Perret motor and the Crowdus battery, a day's good sewing can be done, it is stated, for five cents.

A number of detail pieces, such as shades, reflectors, switches, attachments for gas fixtures, etc., are also shown, and the catalogue includes, at the end, a number of useful tables and rules for making calculations. The last page contains a summarized price list. Altogether the catalogue is one of the best, and should be in the hands of all who are interested in this class of goods.

ABOUT SLATE FOR ELECTRICAL PURPOSES.

BY

T. J. Murphy

IF the electrical industry has found new uses for mica, porcelain, lava, and other known insulators, it has certainly done wonders for the producers of slate. Formerly this article had its greatest sale for mantles, lamp bases, and wash-tubs—to say nothing of the ordinary school slate—but recent experiments show that a species of slate quarried in Vermont is among the best-known insulators, where a large area is to be covered, such as switch-boards and the like. It is even displacing hard rubber and fibre for many smaller articles on account of the various finishes which can be given to the slate, such as imitation of all the different kinds of wood, blood-stone, Tennessee marble, hard rubber—either dull or polished—the slate retaining its moisture-resisting and fire-proof properties, for which it is superior to any other material now in use.

Slate 1 inch thick weighs about 14 lbs. per square foot, and when it is of the select quality is easy to drill and tap, so that machine screws can be used. Recently a New York construction company drilled 12,000 ¼-inch holes in a piece of slate containing only 22 square feet, ⅝-inch thick. It withstood shop handling and transportation, and, considering that the holes were only ¼ of an inch apart, it speaks well for the strength of the slate.

The best slate for electrical purposes, as stated, is found in Vermont, where, probably owing to the absence of iron ore and other metals, the slate is much purer than that quarried elsewhere. Soft slate has a slight greenish color, although it is frequently found in "purple stock" and other colors.

It is found that "marbleizing" slate adds to the moisture-resisting qualities, besides giving it an artistic effect, which is greatly increased when mouldings are used in connection with it.

It has also been found that Pennsylvania slate, besides containing iron, is harder to drill, and there is consequently a more rapid wearing away of the edge of the drill, and careful tests have demonstrated that the selected Vermont slate is the best for electrical purposes. The Manhattan Building, on Wall street, is equipped with a fine slate switch-board built by the Eureka Electric Co., who have also furnished one to the Gerlach Apartment House, on West 27th street. The American Bell Telephone Building in Boston has recently added a slate switch-board, built by the Western Electric Co., and the Manhattan Electric Co. have positioned an incandescent switch-board in their 80th street and Avenue B station, the board being built by V. Prentis, 303 Kent Avenue, Brooklyn. This gentleman formerly used Pennsylvania slate, but found it so expensive on account of the cost of drilling that he thought to make a change, and secured some Vermont slate from me, and found that he could drill the slate in about one-half the time, besides testing up better. I am now constructing a switch-board 13 feet long, 73 inches high, made in six pieces, for the Electrical Construction and Supply Co. of this city, to be used in a plant now erecting for the H. B. Claflin & Co. Building.

Where switch-boards are made in sections it is well to make a drawing or give the exact dimensions, and indicate where screw-holes are to be, so that the switch-board can be drilled before marbleizing, although it can be drilled afterwards if care is taken to start the drill on the marbleized side, for if drilled in from the back the finish is liable to be cracked off, very much like a veneer.

After slate has been quarried and sawed into marketable thickness, which is generally about 1 inch, it is "flowed"—*i.e.*; a composition paint is poured over the surface. It is then put in a kiln or heating oven and kept for several hours at a temperature of about 150 degrees. If it is to be of a higher finish a second coat is given to it, and it is again baked the same as before. It is then rubbed with fine pumice stone until a smooth surface is had, after which a coat of fine varnish is applied and it is baked once more. In fact, the finishing of it is very much similar to the finish given piano cases, only, of course, not so highly polished. The slate can be beveled or any of the ordinary forms of moulding can be given to the edge. Frequently a separate moulding of a different finish is placed around the board to frame it.

In order that those not familiar with the finish, quality, and working properties of slate may be informed, I will furnish to any of your readers who are interested a sample of both plain and marbleized slate, and should any special finish be desired I will furnish a sample of flowed black, polished black, dull black, flowed marbleized, polished marbleized, and plain slate, the six pieces of any size under 12 inches square, 1 inch thick, for $1.50, or 50 cents for any one piece. As the slate is used for transformers, fuses, resistance coils, bases for knife switches, rheostat heads, terminal boards, washers, &c., &c., it will be seen that different finishes are very desirable.

SOME NEW RAILWAY SPECIALTIES OF THE ILLINOIS ELECTRIC MATERIAL CO.

We call the attention of the electric railway public to a new trolley-bell hanger clip, as illustrated in Fig. 1. The many superior points of this clip will be seen at a glance. In the first place the two portions of the clip make a perfect hinge of themselves, doing away with the shaft or rivet, which is a weak point. No solder or screws are used.

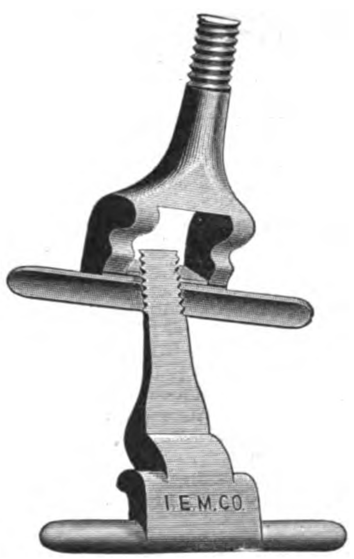

FIG. 1.—NEW TROLLEY-BELL HANGER CLIP.

Fig. 2 illustrates the several parts showing the interior of the hard rubber bell. A heavy bushing is used. All the metal work is of the best heavy red brass. Fig. 3 shows the hanger complete, making a trolley-bell clip that combines not only beauty and strength, but a saving of time and labor in line construction, with a price that is within the reach of all.

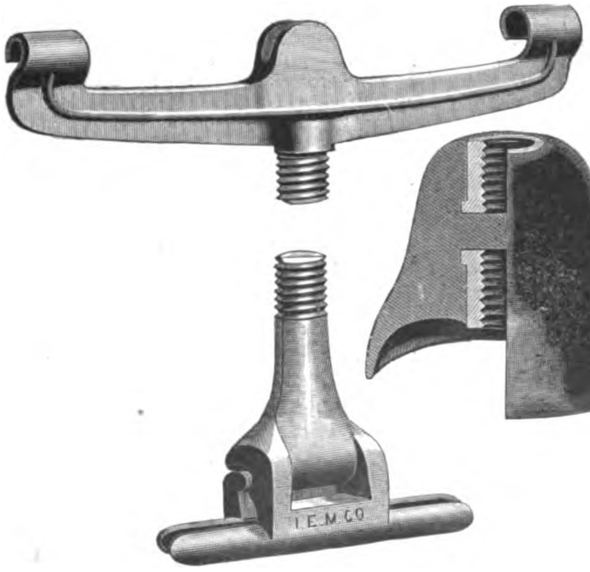

FIG. 2.—NEW TROLLEY-BELL HANGER CLIP.

The hanger is sold exclusively by the Illinois Electric Material Company, 158 Fifth Avenue, Chicago, Illinois.

MR. FRANK H. PUTNEY, president of the Waukesha Electric Light Co., Waukesha, Wis., was in Chicago last week for a short visit.

THE HUBBELL IMPROVED PRIMARY BATTERY.

The dynamo driven by steam or water power shows such economy as compared with the cost of generating current by means of primary batteries that those who pretend to be able to produce current on a large scale for all purposes, by means of primary batteries consuming zinc, are either deceiving themselves or designedly attempting a fraud on the public. But it cannot be denied that even for the production of current for electric lighting and power, there are many situations where a primary battery possesses advantages which make its use not only economical but convenient. Thus, for the operation of light machinery, such as sewing machines, dental lathes, small pleasure boats, and for lighting small lamps in places where other forms of generators would be inapplicable, the primary battery may still find effective employment. It is with a full understanding of the limits within which such a battery can be profitably employed that Capt C. J. Hubbell, of this city has designed a cell embodying several excellent features.

One type of Capt. Hubbell's battery consists of an acid proof box 12"x6"x6", divided into 8 cells. The elements used are zinc and carbon, the latter being cylindrical in form $\frac{1}{16}$ of an inch thick with a split on one side to permit of a free circulation of the liquid. The centre of the bottom of the carbon is projected into an insulated socket having a metal lining terminating in a screw which projects through a hole in the bottom of the porous cup and cell, and is rendered absolutely water tight by means of rubber washers and screws which also hold them firmly in position.

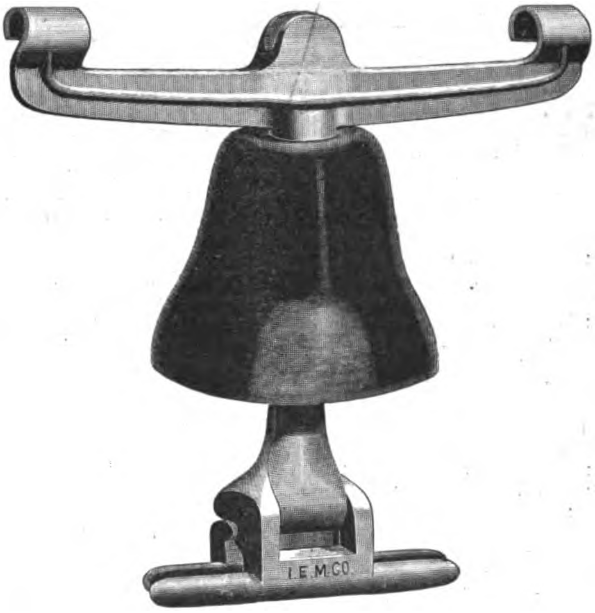

FIG. 3.—NEW TROLLEY-BELL HANGER CLIP.

The method Capt. Hubbell adopts for attaching the electrode to the zinc element is termed a "central contact"; by this method of connection he claims to secure a greater percentage of the energy of the zinc, and absolute freedom from local action. The zinc electrode is also brought through the bottom of the box and secured by washer and screw. The connections are easily and rapidly made either in series or multiple by the use of a small switch-board on one side of the box. The cell also embodies two other important qualities, namely, the oxydizing of noxious fumes produced when the battery is in action, and the cutting off of communication between the two liquids to prevent their mixture, which generally occurs in a two fluid battery, when allowed to remain inactive. It is thus possible to use the battery from day to day, without recharging, until it is exhausted, thereby greatly increasing its commercial value. The first object above mentioned, is accomplished by attaching to the under side of the lid a pad or porus sack filled with asbestos fibre or mineral wool and saturated with bichromate of potash.

Attached to this lid or pad are a series of tubes of insulating material which fit over the porous cups when the cover is depressed and which entirely enclose the cups. This absolutely prevents any local action when the battery is not in use, as no mixture of the liquids can take place. This is readily accomplished by the use of a lazy chain on either side and a tube at either end of the outside of the box through which a rod slips up and down. It should be mentioned that the electrode or arm by which the zinc element is connected in the liquid is of zinc amalgamated with a special amalgam which, while not destroying its conductivity, prevents any local action of the liquid upon it.

The zinc element being cylindrical in form and fitting closely around the porous cup—only space enough being left to admit of the shields or tubes passing between them—and the carbon being also cylindrical and placed close to the inner surface of the porous cup, the advantage of both a large depolarizing surface of carbon, and large surface of zinc, giving a large amperage with low resistance in a small space.

Another mechanical feature of this battery is the manner in which the box is constructed so as to prevent slopping The partitions forming the cells are made some two inches below the top, or, in other words, the box extends two inches above them, thus leaving a space into which the pad or sack fits when depressed, thereby rendering it perfectly fluid-tight during transportation. As this type of the battery is intended to be portable, weighing only about 15 pounds when charged, it is an important improvement.

Perhaps one of the most useful and important applications of the battery is a small four cell battery weighing but 4½ pounds when charged, and which will maintain for a period of 12 hours a three c. p. lamp to full incandescence at a cost of 1¼ cents for the entire period. Capt. Hubbell has two types of this size, one square in form, with the lamp in a reflector on its side, and protected by a thick glass. The other type is made to conform to the shape of the back of the wearer, a conducting flexible cord connecting the battery to a protected lamp attached to a miner's hat; the dimensions of this battery are two in. wide, seven in. from point to point, six in. in depth, and it weighs the same as the other, 4½ pounds.

THOMSON-HOUSTON PLANTS.

The Thomson-Houston Electric Company reports the sale of the following arc apparatus: Athena, O., 18; Braintree, Mass., 30; Chehalis, Wash., 30; Bridgeport, Conn., 45; Portland, Me., 45; Brooklyn, N. Y., 90; Narragansett Pier, R. I., 30; Harrison, O., 35; Ashland, O., 70; Findlay, O., 45; Springfield, Vt., 35; Anderson, Ind., 50; Salem, Va., 100: Athol, Mass., 25; Poughkeepsie, N. Y., 50; Beverely, Mass., 100; No. Tonawanda, N. Y., 100; Lancaster, O., 50. Corning, N. Y., 50; Camden, N. J., 50; Lexington, Ky., 50; Catlettsburgh, Ky., 50; Lockport, N. Y.. 50; Noblesville, Ind., 50; Clinton, Ia.. 50; Parkersburg, W. Va., 100; Lincoln, Neb., 150; Washington, D. C., 100; Put-In-Bay, O., 50; Bay City, Mich., 100; Syracuse, N. Y.. 50; Newton, Mass., 50: Columbus, O., 50; Covington, Ky., 50; Newark, N. J., 100; Elwood, Md., 50; Key West, Fla.. 50; Oakland, Cal., 50. Incandescent Apparatus: Narragansett Pier, R. I., 1,300; Springfield, Vt., 650; Salem, Va., 1,300; Newton. Mass., 650; Key West, Fla., 1,950; Titusville, Fla., 400; New Haven, Conn., 400; Bay Shore, L. I., 400; Dunellen, N. J., 300; Shawnee, O., 300; Akron, O., 1,300; Camden, N. J., 1,300; Brooklyn. N. Y., 1.300; Lock Haven, Pa., 1,300; Iron Mountain. Mich.. 1,950; Buena Vista, W. Va.. 1,300; Norwalk, Conn., 1,300; Lexington, K., 1,300; Atlanta, Ga., 1,300; Waltham, Mass., 1,300; Tacoma, Wash.. 2,600; Morristown, Tenn., 650; White River Junction, Vt., 650; New London, Conn., 650; Patchogue, L. I., 650; Martinville, Md.. 650; Princeton, Md., 650; Bedford City, Va., 650; Millersby, O., 650; Milton, Mass., 650; Cohassett. Mass.. 650; Catlettsburg, Ky., 650; Wacco, Texas, 1,950. Isolated Plants, arc apparatus: Aluminum Carbon Co., Lancaster, Pa., 6; U. S. Immigration Depot, Ellis, Is.. N. Y. Harbor, 40; Palisades Amusement Co., 150. Isolated Plants, Incandescent Apparatus: H. K. Hartzell, Calassugua, Pa. 50; Fort Hamilton Brew. Co., Fort Hamilton, N. Y., 50, Bradbury-Stone Storage Battery Co., Lowell, Mass., 100; National Transit Co., Parkers Bdg., N. Y., 100; N. Copeland. New York, 100; Henry Adams, Rockville, Conn., 150; Cutler Bros., Wakefield, Mass. 150; Blue Ridge Inn, Mt. Airy, No. Carolina, 200; Wainright Real Estate Co., St. Louis, Mo., 2,000; Agnes Scott Institute, Decatur, Ga., 200; Croton Magnetic Iron Mine, Brewster, N. Y., 300; H. C. F. Koch, New York, 800; W. Engle & Co., Orono, Maine, 50; Cleveland Ship Building Co., Cleveland, O., 100; Consumers' Brewery Co.. New York, 400; Manf. Investment Co., Madison, Me., 400; A. O. Couch, New York, 200; W. E. Anderson, Blacksburg, Va., 400; Washington Loan and Trust Co., Washington, D. C., 300.

ELECTRICAL INDUSTRIES IN NEW ENGLAND.

At present there is a decided movement in New England in the direction of utilizing water powers for the generating and transmitting of electrical force over long distances. Such has been the progress in this direction during the last few years that the largest electrical companies in the country are now prepared to utilize some of the hitherto unused water power for the propelling of machinery, for lighting, and for street railway work in the large cities of New England.

Prominent among these enterprises is the development of a large water power on the Merrimac river, situated in the city of Concord, the capital of New Hampshire. When the dam is completed the company developing this property will have a large and steady power, possessing a reservoir extending up stream 18 miles, and reinforced by numerous ponds and lakes, including Lake Winnipiseogee, which are provided with dams by which surplus water is received during the flood seasons. Thus will the power not only be ample, but it will be steady.

It is proposed to furnish electricity over three circuits, and perhaps a fourth, to the present thickly settled portion of the city of Concord, as the distance to the dam is 4 miles north from the State House. One circuit will be used for the transmission of power, one for arc lighting, and the third for incandescent lighting.

This property, being situated within the city of Concord, will also be used for another purpose, namely, the location of manufacturing industries, both large and small, some driven by water taken from the canal and some by electricity.

The company developing this power possesses not only the water power with all its franchises, but a large tract of land, very favorably divided for mill site and resident purposes. It is said that there is no finer property in the country than this, and being situated only 75 miles from Boston, to and from which several express trains pass every day, thus allowing parties to do business in both cities upon the same day, it is certain that any power not wanted for electrical work will be in ready demand by manufacturers. This is especially true since it is the policy of the city of Concord to exempt from taxation for a period of 10 years any manufacturing property that shall locate there, while the company owning the land and power offer special inducements with reference to both.

The property is known as Sewalls Falls, and is owned by the Concord Land and Water Power Co., of which Geo. F. Page, president of the celebrated Page Belting Co., is the president and general manager. This affords a fine opportunity for manufacturers of electrical apparatus to secure favorable location for their business, as also any other manufacturers who may be looking for a location where the largest inducements can be offered and the best results attained, because not only are to be had the advantages which are enumerated, but Concord is especially favored with an abundance of the best of cheap labor, a very important item in manufacturing business.

ENGINEERING EQUIPMENT CO.

Mr. F. A. Magee, M. E., who located himself recently at 126 Pearl Street, Boston, Mass., in the interests of the Engineering Equipment Company and the Underwood Mfg. Co., says that business is good and prospects are excellent for the rapid growth of trade in Cotton Leather Belting, Dodge "Independence" Wood Split Pulleys, Anderson Electric Railway Appliances, especially the "Boston" Trolley, and in the other specialties controlled by the Engineering Equipment Company. Mr. Magee is an engineer of this company and is manager of the Boston office.

Mr. W. F. D. Crane, M. E., who became associated on June 1, with the Engineering Equipment Company, is one of the engineers of the company, at their New York offices, 143 Liberty street, and is in charge principally of the railroad business which is coming to that company increasingly. Mr. Crane reports excellent business on the new Kellogg steel poles, the indurated fibre pipe for subways, and other materials and appliances for electric railways, such as the Anderson goods, notably the "Boston" trolley.

Particular attention of readers is called to the announcement in this issue of the new Kellogg steel poles for electric railways. These poles are already in such demand that orders to come cannot be filled promptly unless they are received two weeks in advance of shipping dates by the sole selling agents, the Engineering Equipment Company, 143 Liberty street, New York; 126 Pearl street, Boston.

THE BAIN ELECTRIC MANUFACTURING CO.

The above named company, of Chicago, are now building alternating current dynamos for long-distance incandescent lighting. These machines have been designed by Mr. Foree Bain, president and electrical engineer of the company, and have many novel and advantageous features, being self-exciting and also self-regulating, the armature coils being wound in separate sets and in a special manner to secure these results. Mr. Bain has also designed some complete small isolated plant outfits for residences, small buildings, factories, etc. They comprise dynamo machine, lamps, sockets all ready wired, wire, cleats and all necessary accessories, and a diagram and complete instructions for setting up, and are built for 10, 15 or 20 lights.

There has long been a need for such an equipment, and the Bain Electric Manufacturing Co. are now prepared to supply this demand.

The prices for these are also quite reasonable, and any one desiring such an outfit would do well to investigate their merits.

THE ELECTRICAL FIBER CARBON CO.

The above company are fitting up their new and spacious factory, at 1234 to 1236 Michigan avenue, with all the necessary machinery and apparatus for the manufacture of carbon of all kinds for electrical purposes. They are also placing on the market a new carbon battery, which is of highly novel construction and possesses in a marked degree all the requirements of a perfect open-circuit battery. The objectionable feature of "creeping" has been entirely overcome, and the battery combines durability and lightness and will fill a long-felt want. They have installed calciners and ovens capable of handling a very large output, and also hydraulic and grinding machinery specially designed for the production of carbons of all sizes and shapes. The company can make anything in the carbon line and of larger size and more intricate form than has heretofore been practicable. They have perfected their processes so as to produce from the raw material employed carbon articles of varied homogeneity and of any desired resistance.

Associated with the concern is an expert chemist, Mr. Eugene Klein, who is also secretary and treasurer, and who will look after the many chemical processes which it is necessary to employ. Mr. John H. Davis, the vice-president, is one of the pioneers in the carbon industry and understands the manipulation of carbon in all its details. Mr. John R. Markel, who is one of the best-known men in the electrical business, from his long connection with lighting work and the supply trade, is the president, and will look after the selling of the goods. He will shortly take an extended trip to all the large cities and electrical centres, and the merits of their products will certainly be appreciated by the electrical fraternity all over the country.

STEPHENSON CAR WORKS TO BE MOVED.

The John Stephenson Company, car builders, has purchased the property known as the Birnie Farm, between Larchmont and Mamaroneck, on the New-Haven Railroad, and will erect extensive car-works on it. The property comprises about thirty-five acres. It is the intention of the company to begin at once to prepare the ground for the erection of the buildings. The new works will probably be the largest and finest in the country. The business has increased so much lately that the present quarters in Twenty-seventh street, which occupy eleven city lots, have become far too limited and a change was found necessary to enable the company to enlarge its facilities. Larger cars, especially larger electric cars, are demanded, and in the new factory special arrangements will be made to build these. The company will retain its valuable property in Twenty-seventh street for the present. It expects to have the new factory in working order inside of two years.

THE CROSBY ELECRIC COMPANY.

The Crosby Electric Company, having announced to its creditors its inability to meet its obligations, a meeting of creditors was held at the company's office Saturday, June 13. A statement of assets and liabilities was presented showing about $10,000 on each side of the account. The company offered in settlement, and with a view of continuing their business, 50 per cent. of claims in stock of the company and 50 per cent. in three notes at 12, 18 and 24 months respectively. A committee of creditors was appointed to consider the proposition. A further meeting of creditors was had June 17th, when the committee reported. They advised against acceptance of the company's offer, and by a vote of creditors present, covering about three-fourths of the claims, the company was required to make a voluntary dissolution. The results of the company's business to June 1, as submitted by the committee in a report by an expert accountant, did not, in the opinion of the heaviest creditors present, justify measures looking to a continuance of the business.

MR. DAVID E. EVANS.

It was once said that Mr. "Dave" Evans was the only "live" electric light superintendent in the South, and though he now has plenty of company in the front ranks of the industry there, his energy is as striking as ever. For some little while to come he will maintain his connection with the Baxter Motor Co. in Baltimore, but he is now going directly into the motor business and will make a specialty of it. He will pay particular attention to electric railway work, and has already been given the contract for construction and track-laying of the North Avenue Electric Railway, in Baltimore. Our long friendship with Mr. Evans and our warm admiration of the many sterling qualities that have made him so valuable in every capacity in this his adopted country compel us to wish for him every manner of success in his new field.

C. & C. FAN AND VENTILATING OUTFITS.

Several nickel-plated C. & C. fan outfits have recently been installed in the White House, at Washington. Large ventilating exhaust fans with C. & C. motors connected directly to the fan shafts have been running for several months past in the Pennsylvania State Capitol Building, at Harrisburg, one in the Assembly and one in the Senate Chamber. The members have been most enthusiastic over the success of the machines, and have passed resolutions testifying to the great improvement the outfits have effected in the atmosphere of the room. The White Star steamship "City of New York," has been equipped with C. & C. fan outfits with 18-inch fans. The Edison Electric Illuminating Co. of New York, bought one hundred C. & C. fan outfits last week. The new operating room in the City Hospital, Rochester, N. Y., is ventilated by a C. & C. exhaust electric fan combination with fan thirty-six inches in diameter.

IN PRAISE OF THE BALL ENGINE.

The Ball Engine Co., of Erie, Pa., have received the following from Mr. C. G. Lyman, secretary of the Queen City Electric Light Co., of Cincinnati, O.: "Replying to your favor of the 27th of February, regarding the Ball engines we have in use, we have one 100 h. p. and two 150 h. p. Ball engines; all three of them are run under exceedingly trying circumstances for any engine. The smallest one has been in use now nearly two years; one of the larger ones about 18 months, and the other one a year, and when we consider the circumstances that two of these engines have to run alongside of the boilers in the fire room, being exposed to the dust and ashes from the same, it is remarkable that we have not had a great deal of trouble with them. But we are pleased to say that they have always done their duty in a highly satisfactory manner, and we look upon the Ball as one of the best high-speed engines."

THE CARD ELECTRIC MOTOR AND DYNAMO CO.

The above concern, of Cincinnati, O., under date of May, have issued a very pretty and tasteful catalogue of their light and power apparatus, which from time to time has been illustrated in our columns. It includes their excellent constant potential machines of the "A" type, as well as of the constant potential and constant current, type "C.," and details are shown, such as the armature, ball bearings, and adjustable self-oiler, their self-oiling bearings, rheostat, etc. Views are also given of their constant current, type "B," motor, not only in full perspective but in clear outline, showing up the governing mechanism, by means of which the motor takes current in strict proportion to the load. Another cut shows the company's one-sixth h. p. motor and fan. A page is also devoted to the Ward arc lamp, which they furnish with their dynamos for incandescent isolated plants.

CONDUIT WIRING CO.

Mr. C. J. Klein, the general manager of this company, 12 West Twenty-ninth street, informs us that they are very busy with their new contracts for wiring with the "Interior Conduit" system. They now have several contracts for houses at Greenwich, Conn.; for St. Bernard's Church, this city, and for a large New York residence, as well as the big Temple Emanuel, which will take 200 lights including fixtures. They also have two buildings to conduit on One Hundred and Twenty-fifth street.

CLAY, PEPPER & REGISTER.

The above electrical engineering concern, of the Provident Building, Philadelphia, are now in the field, although at present only for limited orders, to supply small dynamos and motors—that is to say, machines ranging from one-eighth up to ten horse-power. They have already placed several of their motors on circuits near Philadelphia, and are in receipt of most favorable and encouraging reports. These motors are designed for slow speed.

KERITE CABLES.

Mr. G. B. Prescott, Jr., agent for Day's Kerite, reports the laying of an 18 conductor cable, built to special specification, across the North River, for the American Long Distance Telephone Co. He has also made a contract with the Western Union Tel. Co. for a 10 conductor cable to be laid in the North River. The demand for the Kerite specialties pursues the even tenor of its way.

THE ROCKY MOUNTAIN ELECTRIC LIGHT AND SUPPLY CO.

The Rocky Mountain Electric Light and Supply Company has been organized with a capital stock of $50,000. The incorporators are Harry C. Kessler, John O'Rourke, William Owsley, M. L. Holland, Frank Shaw, John A. Tupper and S. W. Graves. The last named is secretary of the company. The object for which the organization was formed is to carry on the business of merchandizing electrical supplies, of which the company propose to carry a large stock. The offices of the company are in Butte City. Mr. J. A. Tupper, of this company, was formerly manager of the Butte Electric Light Co.

THE BRAZELLE GOVERNOR.

The Mid-Continent Manufacturing Co., of St. Louis, Mo., are installing quite a number of their well-known Brazelle governors on slide-valve engines. This is a most effective device to cause any slide-valve engine to run at a constant speed, irrespective of variation in load, and is especially adapted for use in isolated plants and stations, where engines are employed which are not governed within a small per cent. This governor is an automatic hydraulic governor, and those in need of a good governor should investigate its merits.

NEW YORK NOTES.

The Trenton, N. J., China Co., are arranging to carry on their business as usual, but on a much more substantial financial basis than ever before. Their orders for electrical porcelain have continued to be large, and they have been very successful in that line.

Mr. T. J. Murphy, of 96 Columbus avenue, this city, contributes a very interesting article on the use of slate for electrical purposes. Mr. Murphy is very busily engaged supplying the market with various slate specialties for electrical uses, such as switchboards, &c.

BUFFALO NOTES.

The Short Electric Railway Co. have been awarded the contract for the electrical equipment of the Dunkirk & Fredonia R. R. Co., and the work of rebuilding the line was commenced upon the 11th inst.

The Field Engineering Co. have completed the Niagara street line of the Buffalo Street Railawy, and cars will commence running on the 18th. The apparatus at the power station has been in operation during the past week, and is in perfect order. Thirty-four-foot vestibuled cars built by the Gilbert Manufacturing Co., each equipped with two 15 h. p. "S. R. G." Thomson-Houston motors, will be used on this line.

Mr. Frank Drake.—Cards are out for the marriage of Mr. Frank Drake, electrical engineer of the Pittsburgh and Birmingham Traction Co., Pittsburgh, Pa., to Miss Luella Love, of Buffalo, N. Y., on the 24th inst. Mr. Drake was formerly engineer for the Buffalo Street R. R. Co.

WESTERN TRADE NOTES.

Kohler Bros. & Grier are doing a phenomenal business with the famous Eddy motors, for which they are the Western agents. Among the recent motors, they have installed two 2 h. p., three 3 h. p., one 5 h. p., one 15 h. p. and one 5 h. p. They have also sold a 50 h. p. generator.

Prof. Francis B. Crocker was a Chicago visitor last week.

Mr. S. F. B. Morse, representing the Loomis system, was in Chicago last week, and with Mr. Frederick L. Merrill, Western agent, called at the office of The Electrical Engineer.

S. D. Childs & Co., the engravers and medalists of Chicago, have brought out a very handsome souvenir in the shape of an aluminum medal, one of which they have presented to the Western office of The Electrical Engineer. It is the size of a silver dollar, one face representing the General Grant monument to be erected in Lincoln Park this fall. It is a very beautiful piece of workmanship and forms a handsome souvenir.

The Western Electric Co. have among other recent orders secured contracts in Pittsburgh for the new Alvin Theatre, owned by Charles L. Davis, 2,000 lights; the new Telephone Building, 700 lights; the Howard Glass Works, 800 lights; the Pittsburgh *Despatch* building, 400 lights. All these contracts were secured by Mr. Edward L. Devore, the energetic representative of the Western Electric Co., with headquarters in Pittsburgh. Although Mr. Devore has only been engaged in electric work for a short period, he has made a most remarkable record in the large volume of business he has obtained.

Cutter's Magnetic Cut-out, which we illustrated last week, seems to be just the thing for electric railways, as it saves the constant burning out of armature and field coils. Mr. George Cutter is adapting it to various other uses, and his shop force has been increased to turn out these magnetic cut-outs and his other specialties.

The Ball Engine Co., of Erie, Pa., have received the following from the Naugatuck, Conn., Electric Light Co.: "Your favor of the 21st inst. received, and beg leave to say that we have used one of your 60 h. p. engines for over four years, with entire satisfaction, and are so pleased with its operations, that we are now erecting a 200 horse power cross compound engine of your manufacture."

ST. LOUIS TRADE NOTES.

The Columbia Incandescent Lamp Co. are experiencing a brisk demand for Columbia incandescents, which are giving good satisfaction on account of their long life, small absorption of current, and freedom from discoloration.

The Wagner Electric Mfg. Co., whose alternating fan motor was recently illustrated in the columns of The Electrical Engineer, are finding a ready market for their motors. They will shortly place on the the market some larger sized alternating motors for all kinds of power work.

The St. Louis Electrical Co. have just been awarded a contract for the complete wiring equipment and all the fixtures for the electric light plant in the Third National Bank, and have also secured a similar contract from the Chemical National Bank. In supplies of all kinds they are doing a large and prosperous business.

The Southern Electrical Supply Co. have just completed their new offices, which add much to the attractive appearance of their handsome store. The partitions are all of highly polished cherry wood, with French plate-glass windows. Mr. W. C. McKinlock, manager of the company, reports business as flourishing, and the outlook for the future as of the most encouraging nature.

Mr. Julius Lefmann, 309 Fagin Building, St. Louis, handles a very complete line of street railway specialties of new and valuable designs. Street railway men should look into their merits.

The Emerson Electric Mfg. Co. are almost snowed under with orders for their new alternating fan motors. Central stations operating the alternating system are sending in orders from all parts of the country for these motors, which are connected direct in the lamp circuit, and operate as perfectly as any direct current motor.

The American Electrical Mfg. Co. are very busy manufacturing American incandescent lamps, which have been giving excellent satisfaction wherever they have been used.

The Stevenson-Hoggson Electric Co. are having quite a run on their single-magnet bells, which are excellent in design and workmanship.

The Western Electrical Supply Co. have now got comfortably settled in their handsome new store on Locust and Sixth streets. They will carry a large stock of high-class supplies and goods, and be prepared to fill orders at short notice.

The Shultz Belting Co. have some very large orders for their belts on hand for various parts of this country and also for Europe, where they have a large and growing trade. They are meeting with excellent success with their link belting, which is especially suited for street railway work.

The Sunbeam Incandescent Lamp Co. have been recently shipping a large number of their well-known lamps to British Columbia, Mew Mexico, California, and Panama.

The St. Louis and Suburban Railroad Co., who operate a line 28 miles in length, composed of about 4 miles of cable and 24 miles of narrow gauge steam road, have determined to adopt electric power for the entire line. An entirely new equipment of rolling stock, consisting of 60 Thomson-Houston motor cars, and 60 trail cars, will take the place of the old cable and steam equipment. The cable engines will be transferred to the new electric power house at De Hodiament station and used to drive the generators.

L. L. Somers, assistant electrician of the Western Union Telegraph Co., Chicago, is in charge of the installation of the electrical plant of the new W. U. Telegraph building, St. Louis. The plant will be complete in a few weeks, and will be a model of excellence in modern telegraph engineering. It has been described in The Electrical Engineer.

☞ Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Miscellaneous, etc., will be found in the advertising pages.
